

## ETSI STC TM6

(ACCESS TRANSMISSION SYSTEMS ON METALLIC CABLES)

### Permanent Document TM6(98)10

# Laboratory Performance tests for SDSL and ADSL systems.

This is a living document, to be updated every ETSI meeting, when new input arises

This document is intended to keep track of the various proposals in ETSI-TM6 on performance tests for xDSL, that have gained some support. Consensus has grown within ETSI-TM6 to define one unified performance tests for all long range xDSL systems, including SDSL and ADSL, that lines up with the VDSL performance tests. This document is a basis for such a future work item within ETSI-TM6.

The main portion of this document is based on its original version [6] and updated with

- the time domain requirements described in [7],
- the noise models for SDSL described in [8,9,10],
- the noise models for ADSL described in [11], and
- the testloops as described in [15] and preceded by [16,17,18].
- a first description of impulse noise tests

# 1. Transmission performance tests

The purpose of transmission performance tests is to stress xDSL transceivers in a way that is representative to a high penetration of systems scenario in operational access networks. This high penetration approach enables operators to define deployment rules that apply to most operational situations. It means also that in individual operational cases, characterised by lower noise levels and/or insertion loss values, the xDSL system under test may perform better than tested

The reference impedance  $R_V$  is 135Ω. All spectra are representing single sided power spectral densities (PSD's).

## 2. Test procedure

The purpose of this sub-clause is to provide an unambiguous specification of the test set-up, the insertion path and the way signal and noise levels are defined. The tests are focused on the noise margin, with respect to the crosstalk noise or impulse noise levels when xDSL signals under test are attenuated by standard test-loops and interfered with standard crosstalk noise or impulse noise. This noise margin indicates what increase of crosstalk noise or impulse noise level is allowed under (country-specific) operational conditions to ensure sufficient transmission quality.

NOTE: The interpretation of noise margin, and the development of deployment rules based on minimum margin requirements under operational conditions, are not the responsibility of transceiver manufacturers. Nevertheless, it is recommended that manufacturers provide Network Operators with simulation models that enable them to perform reliable predictions on transceiver behaviour under deviant insertion loss or crosstalk conditions. Different linecodes or duplexing techniques may behave differently.

### 2.1. Test set-up definition

Figure 1 illustrates the functional description of the test set-up. It includes:

- The test loops, as specified in sub-clause 3;
- An adding element to add the impairment noise (a mix of random, impulsive and harmonic noise), as specified in sub-clause 4;
- A high impedance, and well balanced (e.g. better than 60 dB across the whole band of the xDSL system under test) differential voltage probe connected with level detectors such as a spectrum analyser or a true rms volt meter.

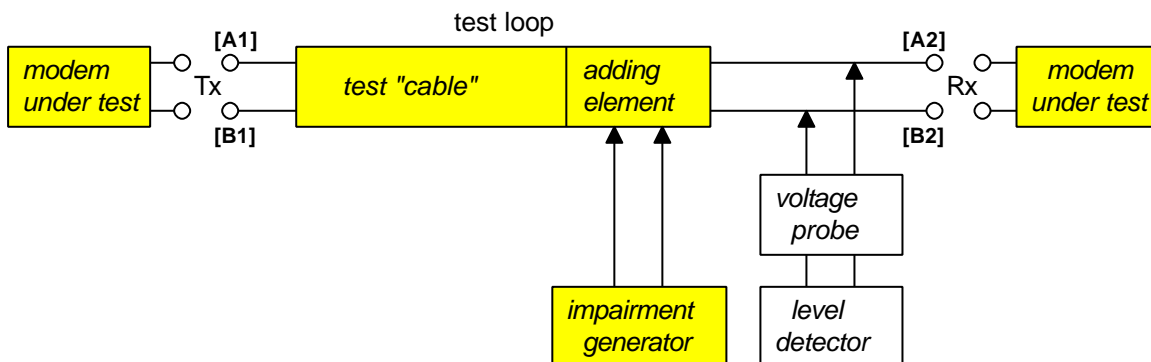

Figure 1: Functional description of the set-up of the performance tests. When external splitters are required for the xDSL system under test (for POTS or ISDN signals), this splitter shall be included in the modem under test.

The two-port characteristics (transfer function, impedance) of the test-loop, as specified in sub-clause 3, are defined between port Tx (node pairs A1,B1) and port Rx (node pair A2,B2). The consequence is that the two-port characteristics of the test "cable" in Figure 1 must be properly

adjusted to take full account of non-zero insertion loss and non-infinite shunt impedance of the adding element and impairment generator. This is to ensure that the insertion of the generated impairment signals does not appreciably loads the line.

The balance about earth, observed at port Tx at port Rx and at the tips of the voltage probe shall exhibit a value that is 10 dB greater than the transceiver under test. This is to ensure that the impairment generator and monitor function does not appreciably deteriorate the balance about earth of the transceiver under test.

The signal flow through the test set-up is from port Tx to port Rx, which means that measuring upstream and downstream performance requires an interchange of transceiver position and test "cable" ends.

The received signal level at port Rx is the level, measured between node A2 and B2, when port Tx as well as port Rx are terminated with the xDSL transceivers under test. The impairment generator is switched off during this measurement.

Test Loop #0, as specified in sub-clause 3, shall always be used for calibrating and verifying the correct settings of generators G1-G7, as specified in sub-clause 4, when performing performance tests.

The transmitted signal level at port Tx is the level, measured between node A1 and B1, under the same conditions.

The impairment noise shall be a mix of random, impulsive and harmonic noise, as defined in sub-clause 4. The level that is specified in sub-clause 4 is the level at port Rx, measured between node A2 and B2, while port Tx as well as port Rx are terminated with the normalized test impedance  $R_V$ . These impedances shall be passive when the transceiver impedance in the switched-off mode is different from this value.

## 2.2. Startup training procedure

[ED NOTE <for further study>. Let's make a description for modem startup training at noise levels that are 10 dB below the test noise. This verifies how adequate an activated the modem will respond to noise levels that vary in time \(non-stationary crosstalk\). See also the Alcatel contribution to the Sophia meeting: 985t37a0 and 985t38a0](#)

## 2.3. Signal and noise level definitions

The signal and noise levels are probed with a well balanced differential voltage probe, and the differential impedance between the tips of that probe shall be higher than the shunt impedance of 100 k $\Omega$  in parallel with 10 pF. Figure 1 shows the probe position when measuring the Rx signal level at the LT or NT receiver. Measuring the Tx signal level requires the connection of the tips to node pair [A1,B1].

NOTE: The various levels (or spectral masks) of signal and noise that are specified in this document are defined at the Tx or Rx side of this set-up. The various levels are defined while the set-up is terminated, as described above, with normalized test impedance  $R_V$  or with xDSL transceivers under test.

Probing an rms-voltage  $U_{rms}$  [V] in this set-up, over the full signal band, means a power level of P [dBm] that equals:

$$P = 10 \times \log_{10}(U_{rms}^2 / R_V \times 1000) \text{ [dBm]}$$

Probing an rms-voltage  $U_{rms}$  [V] in this set-up, within a small frequency band of  $\Delta f$  (in Hertz), means an average spectral density level of P [dBm/Hz] within that filtered band that equals:

$$P = 10 \times \log_{10}(U_{rms}^2 / R_V \times 1000 / \Delta f) \text{ [dBm/Hz]}$$

The bandwidth  $\Delta f$  identifies the noise bandwidth of the filter, and not the -3dB bandwidth.

## 3. Test loops

The purpose of the test loops shown in Figure 1 is to stress xDSL transceivers under a wide range of different conditions that can be expected when deploying xDSL in real access networks

### 3.1. Functional description

The test loops in section 3.2 are an artificial mixture of cable sections. A number of different loops has been used to represent a wide range of cable impedances, and to represent ripple in amplitude and phase characteristics of the testloop transfer function.

- The length of the individual loops are such chosen that the transmission characteristics of all loops are comparable. This has been achieved by normalizing the *electrical* length of the loops (insertion loss at a well chosen test frequency). The purpose of this is to stress the equalizer of the xDSL modem under test similarly over all loops, when testing xDSL at a specific bitrate. The total length of each loop is described in terms of *physical* length, and the length of the individual sections as a fixed fraction of this total. If implementation tolerances of one testloop causes that its resulting *electrical* length is out of specification, then its total physical length shall be scaled accordingly to correct this error.
- The impedance characteristics of these loops are such chosen that they cover the impedances of a wide range of distribution cables that are commonly used in Europe. The purpose of a wide range of impedances is to stress the echo cancelation of the xDSL modem under test. This effect has been emphasized by implementing some loops with highly mismatched cable sections.
- Some test loops include bridged taps to achieve rapid variations in amplitude and phase characteristics of the cable transfer function. In some European access networks, these bridge taps have been implemented in the past, which stresses the xDSL modem under test differently.

### 3.2. Testloop topology

The loops are defined as a combination of cable sections. Each section is defined by means of two-port cable models of the individual sections (see Annex [\*]). Cable simulators as well as real cables can be used for these sections. The length of the individual loops are defined by the tables of section 3.3.

[ED NOTE Currently, different testloops are being used for testing ADSL, HDSL and VDSL. For the short term, SDSL has adopted existing HDSL testloops. There is consensus within ETSI-TM6 that this situation needs to be improved in future by one common unified approach. The definition of unified testloops is currently under study.](#)

#### 3.2.1. SDSL Testloops

The topology of the SDSL loops is specified in figure 2. The transfer function of all the loops for each payload bit-rate is shown in figure 3. The variation of input impedance for the various test loops is shown in figure 4. The two-port cable models that are used to describe the individual sections of the loops are specified in Annex A.2.

- Loop #1 is a symbolic name for a loop with zero (or near zero) length, to prove that the SDSL transceiver under test can handle the potentially high signal levels when two transceivers are directly interconnected.
- The other loops are copied from the HDSL tests

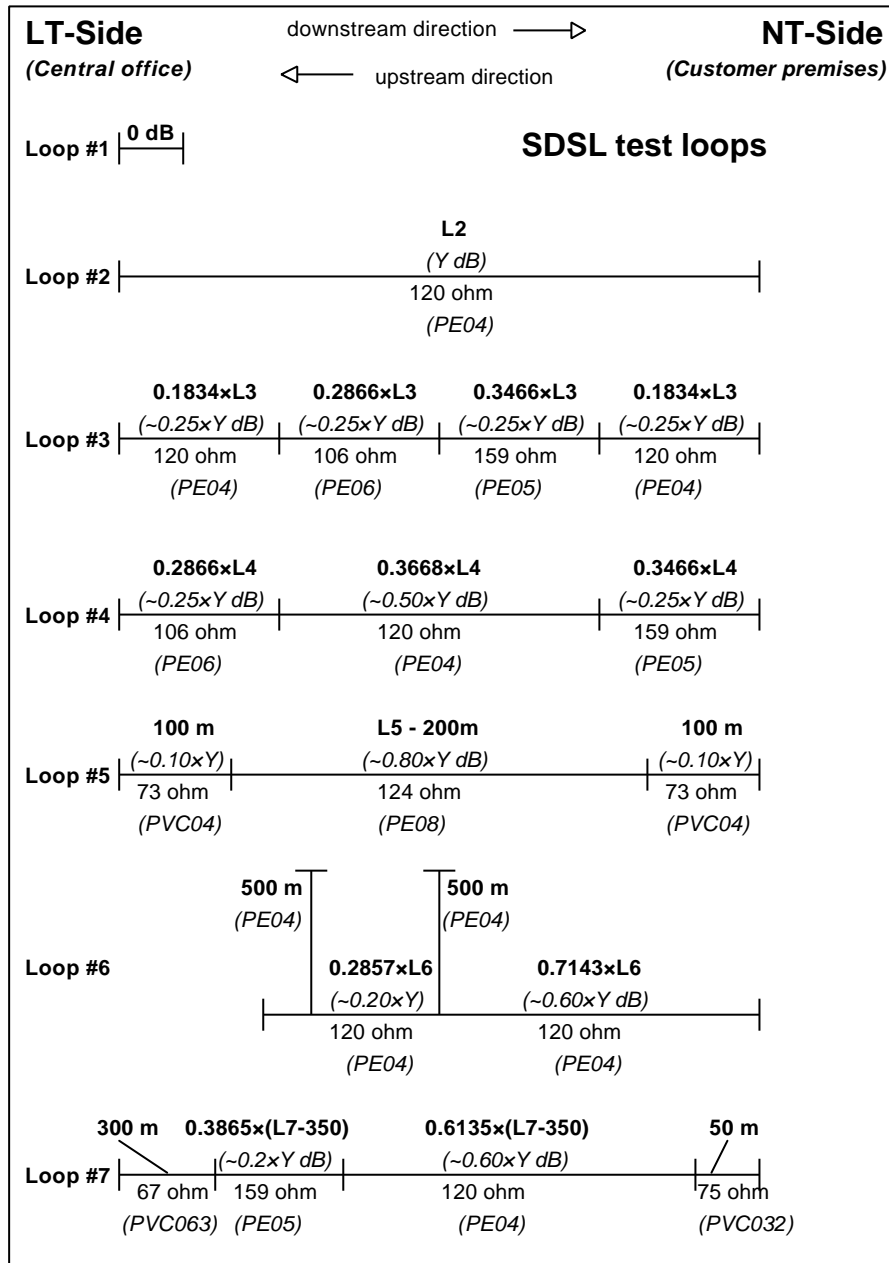

Figure 2: Test loop topology for SDSL, that is made as similar as possible to existing HDSL test loops. The physical lengths L1 to L7 are specified in table 1. The symbolic labels (e.g. "PE04") refer to the two-port cable models that are specified in Annex A. The impedances refer to the characteristic impedance of each section, at 300 kHz, and is for information only. The same applies to the "Y"-values, that refer to what portion of the characteristic insertion loss is accounted for each section.

Figure 3: Examples of calculated transfer functions (into 135W) of test-loop #2 to #7, (and #8 as the reversed loop #4). In figure 3a the electrical length of each loop is normalized at 150 kHz (30 dB loss in this example), and in figure 3b at 300 kHz (39 dB in this example). The choice for test frequencies, as specified in table 1, is closely related to the PSD of the xDSL modem under test, and this PSD may vary with the payload bitrate.

Figure 4: Calculated variation of input impedance (absolute value) of testloop #2 to #8. When the cable is relatively long, these impedances become more or less length independent.

### 3.2.2. ADSL Testloops

The topology of the ADSL loops is specified in figure 5. The two-port cable models that are used to describe the individual sections of the loops are specified in Annex A.3.

Loop #0 is a symbolic name for a loop with zero (or near zero) length, to prove that the ADSL transceiver under test can handle the potentially high signal levels when two transceivers are directly interconnected.

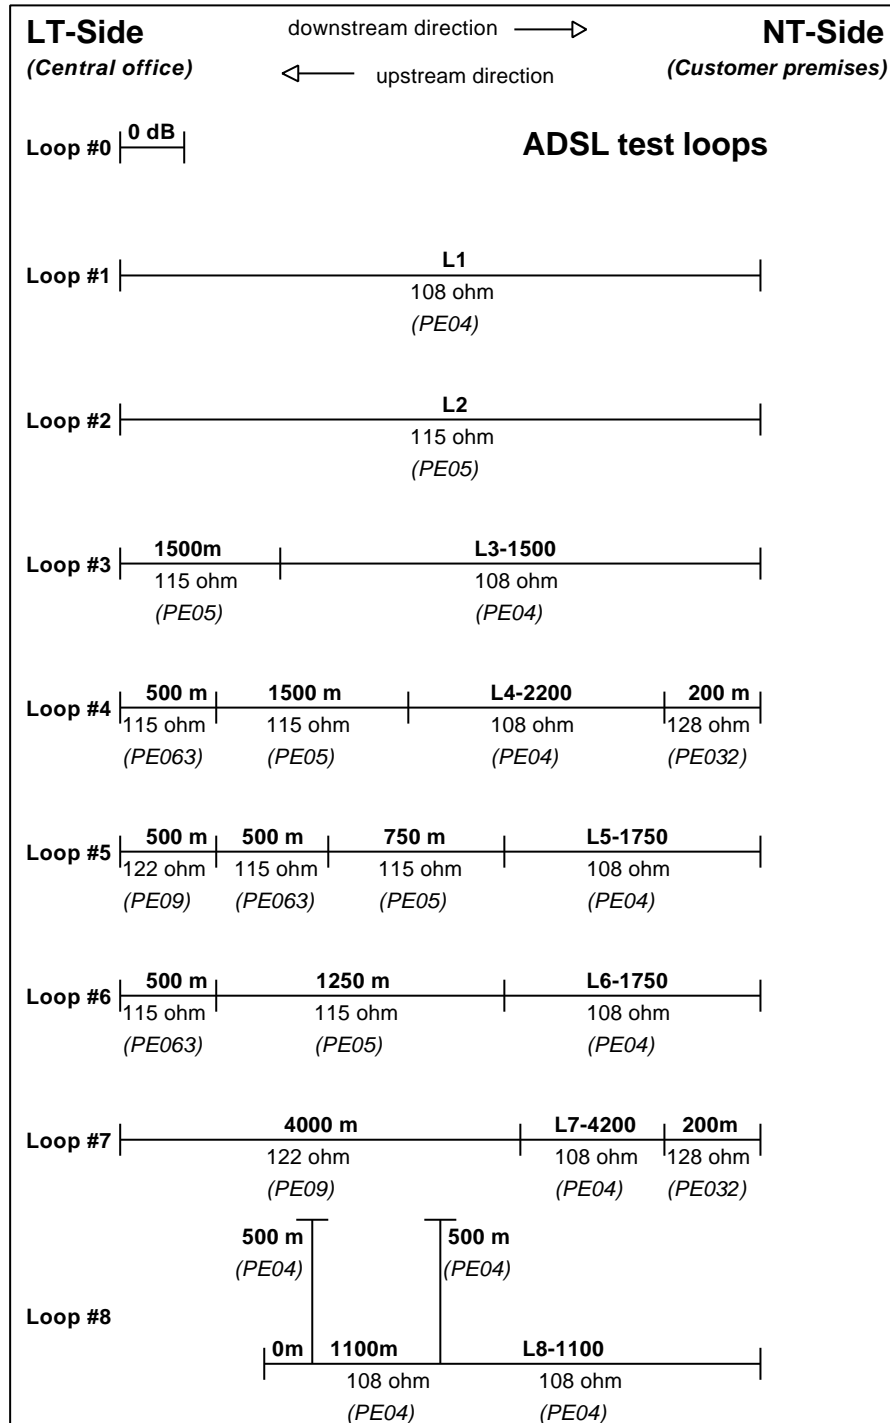

Figure 5: Test loop topology for ADSL

### 3.2.3. Unified Testloops

The topology of the unified loops is specified in figure 6. The transfer function of all the loops for each payload bit-rate is shown in figure 7. The variation of input impedance for the various test loops is shown in figure 8. The two-port cable models that are used to describe the individual sections of the loops are specified in Annex A.4.

- Loop #0 is a symbolic name for a loop with zero (or near zero) length, to prove that the xDSL transceiver under test can handle the potentially high signal levels when two transceivers are directly interconnected.

- The impedances of Loop #1 and #2 are nearly constant over a wide frequency interval. These two loops represent uniform distribution cables, one having a relatively low characteristic impedance and another having a relative high impedance (low capacitance per unit length). These impedance values are chosen to be the lowest and highest values of distribution cables that are commonly used in Europe.
- The impedances of Loop #3 and #4 follow frequency curves that are oscillating in nature. This represents the mismatch effects in distribution cables caused by a short extent with a cable that differs significantly in characteristic impedance. Loop #3 represents this at the LT side to stress downstream signals. Loop #4 does the same at the NT side to stress upstream signals.
- Loop #5 is a loop with bridged taps. Details for this loop are for further study.

All other test loops in Figure 6 have equal *electrical* length (insertion loss at a specified test frequency), but differ in input impedance (see Figure 8). It are these values for insertion loss and impedance that define an actual test loop set. The loops are not defined in terms of a specific *physical* length.

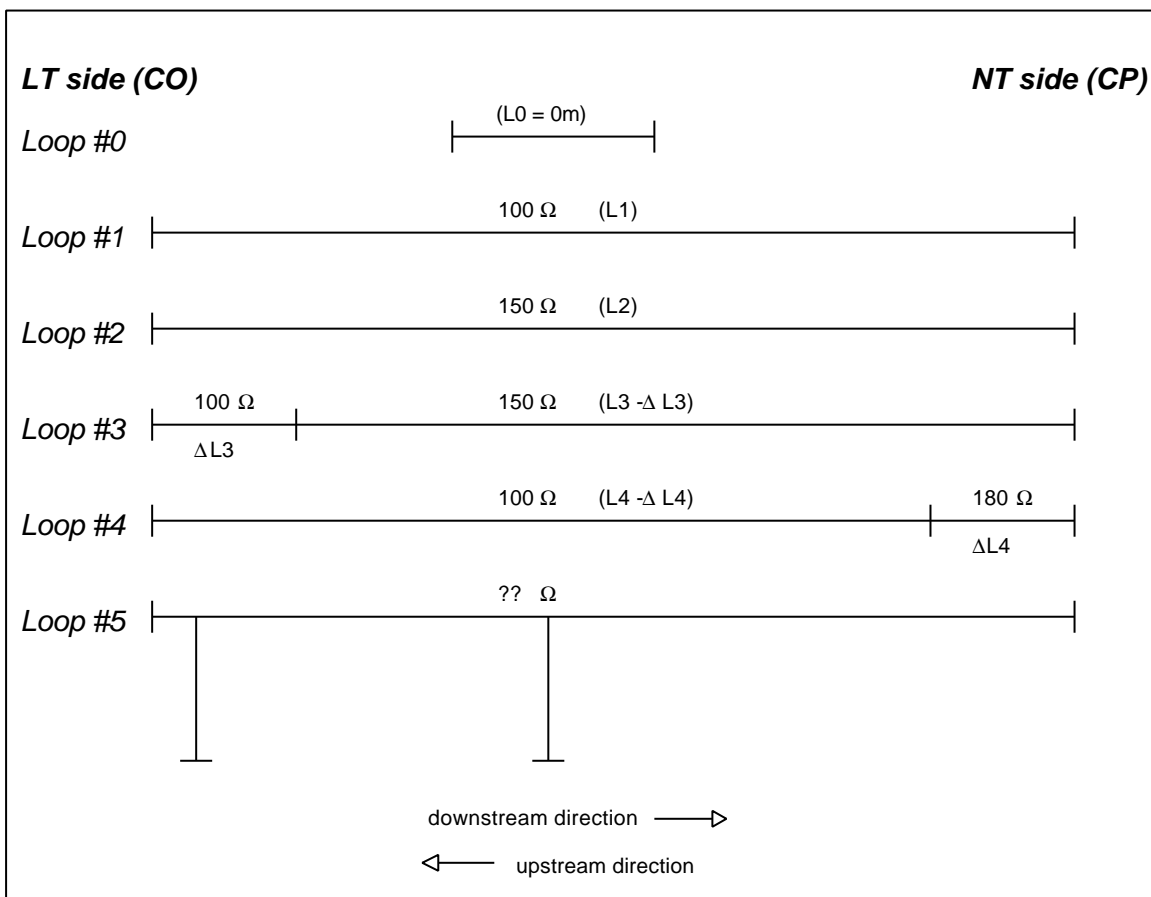

Figure 6: Test loop topology

The variation of input impedance for the various test loops is shown in Figure 8. The transfer function of all the loops for each payload bit-rate is shown in Figure 7.

Figure 7: Transmission gain (in 135W) of the test-loops, for different electrical lengths (= insertion loss, @300kHz, @135W). Loop #1 and #4 are very similar in transmission gain; the same applies to loop #2 and #3, but their difference is small due to the normalization at 300 kHz.

Figure 8: Calculated variation of input impedance (absolute value) of long testloops (>> 6 km)

### 3.3. Testloop length

To minimise the electrical differences between different testloop configurations, their “length” is specified as “electrical length” instead of the “physical length” of the sections in cascade (meaningful only when real cables are used). The electrical length is equivalent to the insertion loss of the loop at specified test frequency and resistance.

The relation between Electrical length (insertion loss) and total physical length (when real cables are used) can be calculated from the two-port cable models.

**ED NOTE** It is possible that the approach of “normalizing” the electrical length can be improved by a more sophisticated approach (e.g. equivalent loss, impulse response). In that case, the length of each loop remains specified in terms of electrical length (at a well chosen center frequency) but each loop has a (slightly) different electrical length. Such an improvement has only impact to the numbers in table 1 and 3, and not on the topology description in figure 2. The numbers in table 1 and 3 are for further study.

### 3.3.1. Loop length for testing SDSL

The length of each test loop for SDSL modems is specified in table 1 and 2. The specified insertion loss at the specified test frequency and 135Ω impedance (*electrical* length) is mandatory. If implementation tolerances of one testloop causes that its resulting *electrical* length is out of specification, then its total *physical* length shall be scaled accordingly to adjust this error.

The test frequency is chosen to be a typical mid-band frequency in the spectrum of long range xDSL systems. The length is chosen to be a typical maximum value that can be handled correctly by the xDSL transceiver under test. This value is bitrate dependent; the higher the payload bit-rate, the lower the insertion loss is that can be handled in practice.

2304 (a)	225	25.0	< 3	2147	2801	2813	4771	2237	250	25.5	1428

Table 2: Values of the electrical length Y of the SDSL noise testloops, when testing SDSL at noise model B, C or D. The electrical length Y (insertion loss at specified frequency  $f_T$ ) is mandatory, the (estimated) physical lengths L1-L7 are informative.

(s) those electrical lengths apply to the symmetric PSD  
(a) those electrical lengths apply to the asymmetric PSD

**ED NOTE** The numbers here were taken from TD02 (Helsinki). Mark that the length L7 of testloop 7 is defined as the FULL testloop length, while its specification was changed by accident (by the SDSL editor?) as the full length *minus 350m*.. The length specification in Permanent Document TM6(98)10 is the preferred one, since it makes all length definitions consistent. The SDSL standard needs a correction on this point

**ED NOTE** The informative physical lengths are evaluated, using a "cubic spline interpolation" from the RLC-parameters summarized in TD18 (Helsinki), that are 100% identical to the parameters that were extended to 2 MHz in TD23 (Edinburgh)

**ED NOTE** The numbers in this table are for futher study.

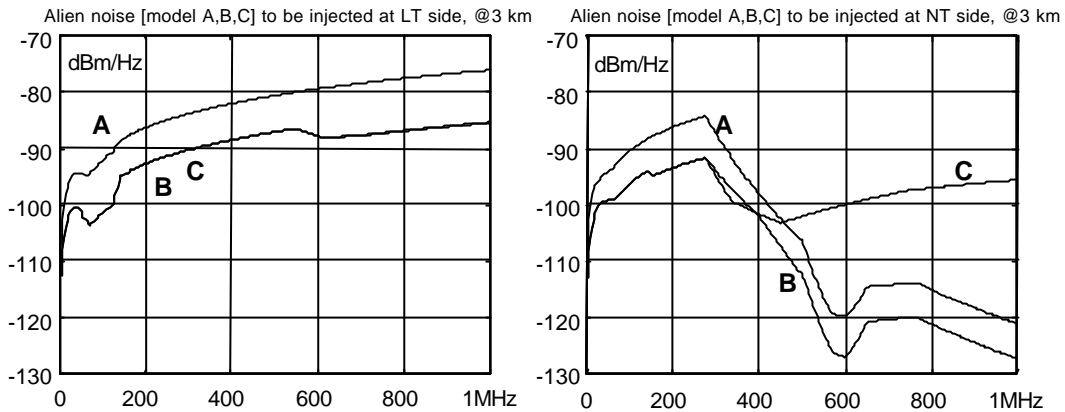

### 3.3.3. Loop length for testing ADSL over ISDN

Noise model A

## 4. Impairment generator

The noise that the impairment generator injects into the test setup is frequency dependent, is dependent on the length of the testloop and is also different for downstream performance tests and upstream performance tests. Figure 9 illustrates this for the *alien* noise (other than the xDSL modem under test) in the case that the length of testloop #1 is fixed at 3 km. Figure 10 illustrates this for various loop lengths in the case that the *alien* noise of model 'B' is applied. These figures are restricted to alien noise only, because the PSD of SDSL is for further study. The self noise (of SDSL) shall be combined with this alien noise.

**Figure 9: Examples of alien noise spectra that are to be injected into the test setup, while testing SDSL systems. This is the noise, resulting from three of the four noise models for SDSL, in the case that the length of testloop #2 is fixed at 3 km.**

**Figure 10: Examples of alien noise spectra that are to be injected into the test setup, while testing SDSL systems. This is the alien noise, resulting from noise model B for SDSL, in the case that the length of testloop #2 varies from 1 km to 4 km. This demonstrates that the test noise is length dependent, to represent the FEXT in real access network cables.**

The definition of the impairment noise for xDSL performance tests is very complex and for the purposes of this TS it has been broken down into smaller, more easily specified components. These separate, and uncorrelated, impairment "generators" may therefore be isolated and summed to form the impairment generator for the xDSL system under test. The detailed specifications for the components of the noise model(s) are given in this sub-clause, together with a brief explanation.

## 4.1. Functional description

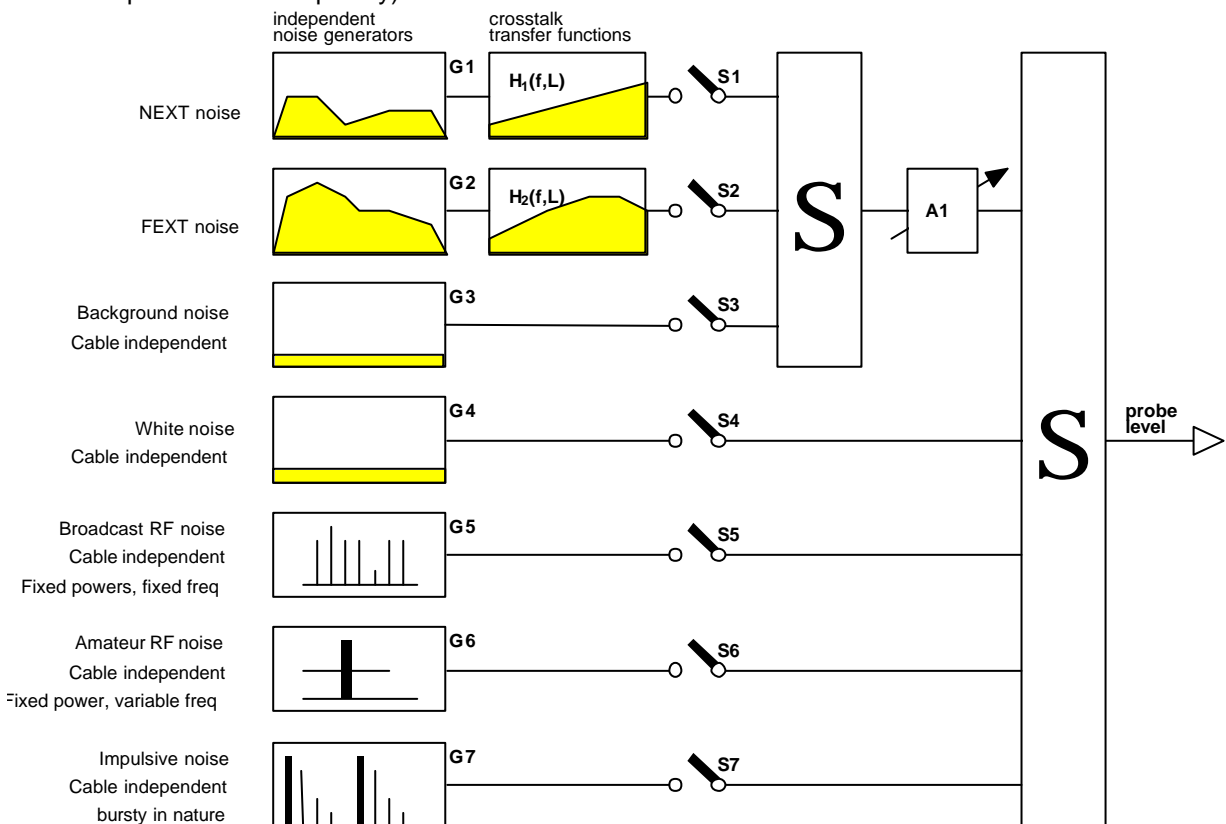

Figure 11 defines a functional diagram of the composite impairment noise. It defines a functional description of the combined impairment noise, as it must be probed at the receiver input of the xDSL transceiver under test. This probing is defined in sub-clause 2.3.

The functional diagram has the following elements:

- The seven impairment “generators” G1 to G7 generate noise as defined in sub-clause 4.3.1 to 4.3.7. Their noise characteristics are independent from the test-loops and bit-rates.
- The transfer function  $H_1(f,L)$  models the length and frequency dependency of the NEXT impairment, as specified in sub-clause 4.2. The transfer function is independent of the loop-set number, but changes with the electrical length of the test loop. Its transfer function changes with the frequency  $f$ , roughly according to  $f^{0.75}$ .
- The transfer function  $H_2(f,L)$  models the length and frequency dependency of the FEXT impairment, as specified in sub-clause 4.2. Its transfer function is independent of the loop-set number, but changes with the electrical length of the test loop. Its transfer function changes with the frequency  $f$ , roughly according to  $f$  times the cable transfer function.
- Switches S1-S7 determine whether or not a specific impairment generator contributes to the total impairment during a test.
- Amplifier A1 models the property to increase the level of some generators simultaneously to perform the noise margin tests as defined in sub-clause 5.2. A value of  $x$  dB means a frequency independent increase of the level by  $x$  dB over the full band of the xDSL system under test, from  $f_L$  to  $f_H$ . Unless otherwise specified, its gain is fixed at 0 dB.

In a practical implementation of the test set-up, there is no need to give access to any of the internal signals of the diagram in Figure 11. These function blocks may be incorporated with the test-loop and the adding element as one integrated construction.

The average transfer function  $s_{T0}(\omega,L)$  of the four test-loops is the  $s_{21}$  transfer function parameter in source/load resistance  $R_V$  of test-loop #1 at specified payload bit-rate. It is considered as an average of all the four loops at equal electrical length (normalised in insertion loss at a specified test frequency).

- NOTE 1: Generator G7 is the only one which is symbolically shown in the time domain.  
NOTE 2: The precise definition of impulse noise margin is for further study.

Figure 11: Functional diagram of the composition of the impairment noise

This functional diagram will be used for impairment tests in downstream and upstream direction. Several scenario's have been identified to be applied to xDSL testing. These scenario's are intended to be representative of the impairments found in metallic access networks.

Each scenario (or noise model) results in a length dependent PSD description of noise. Each noise model is subdivided into two parts: one to be injected at the LT-side, and another to be injected at the NT-side of the xDSL modem link under test. Some of the seven individual impairment "generators" G1 to G7 are therefore defined by more than one noise model.

Each test has its own impairment specification, as specified in clause 5. The overall impairment noise shall be characterised by the sum of the individual components as specified in the relevant sub-clauses. This combined impairment noise is applied to the receiver under test, at either the LT (for upstream) or NT (for downstream) ends of the test-loop.

## 4.2. Cable cross-talk models

The purpose of the cable cross-talk models is to model both the length and frequency dependence of crosstalk measured in real cables. These cross-talk transfer functions adjust the level of the noise generators in Figure 11 when the electrical length of the test-loops is changed. The frequency and length dependency of these functions is in accordance with observations from real cables. The specification is based on the following constants, parameters and functions:

- Variable **f** identifies the frequency in Hertz.
- Constant **f<sub>0</sub>** identifies a chosen reference frequency, which was set to 1 MHz.
- Variable **L** identifies the physical length of the actual test loop in meters. This physical length is calculated from the cable models in annex A, from the specified electrical length. Value are summarized in table 1 for each combination of payload bitrate, noise model and test loop.
- Constant **L<sub>0</sub>** identifies a chosen reference length, which was set to 1 km.
- Transfer function **s<sub>T</sub>(f, L)** represents the frequency and length dependent amplitude of the transfer function of the actual test loop. This value equals  $s_T = |s_{21}|$ , where  $s_{21}$  is the transmission s-parameter of the loop normalized to 135Ω. Annex A provides formula's to calculate this s-parameter.
- Constant **K<sub>xn</sub>** identifies an empirically obtained number that scales the NEXT transfer function  $H_1(f, L)$ . The resulting transfer function represents a power summed cross-talk model [\*] of the NEXT as it was observed in a test cable. Although several disturbers and wire pairs were used, this function  $H_1(f, L)$  is scaled down as if it originates from a single disturber in a single wire pair.
- Constant **K<sub>xf</sub>** identifies an empirically obtained number that scales the FEXT transfer function  $H_2(f, L)$ . The resulting transfer function represents a power summed cross-talk model [\*] of the FEXT as it was observed in a test cable. Although several disturbers and wire pairs were used, this function  $H_2(f, L)$  is scaled down as if it originates from a single disturber in a single wire pair.

The transfer functions in Table 5 shall be used as cross-talk transfer functions in the impairment generator.

$H_1(f, L) = K_{xn} \times (f/f_0)^{0.75} \times \sqrt{1 -  s_T(f, L) ^4}$
$H_2(f, L) = K_{xf} \times (f/f_0) \times \sqrt{(L/L_0)} \times  s_T(f, L) $
$K_{xn} = 10^{(-50/20)} \approx 0.0032, f_0 = 1 \text{ MHz}$
$K_{xf} = 10^{(-45/20)} \approx 0.0056, L_0 = 1 \text{ km}$
$s_{T0}(f, L) = \text{averaged test loop transfer function}$

Table 5 : Definition of the crosstalk transfer functions

NOTE: These values are rounded values, and chosen to be close to the ANSI T1E1.4 VDSL draft System Requirements (which are consistent with [\*]). This choice is equivalent to 50 dB NEXT loss and 45 dB EL-FEXT loss at a cable section of 1 km. At this moment, it is by no means sure that these are reasonable values to represent the 'average' European cables. The few measurements that are available for European cables demonstrate sometimes significant differences from the above values. This is an area of further study.

## 4.3. Individual impairment generators

### 4.3.1. Equivalent NEXT disturbance generator [G1.xx]

The NEXT noise generator represents the equivalent disturbance of all impairment that is identified as crosstalk noise from a predominantly Near End origin. This noise, filtered by the NEXT crosstalk coupling function of sub-clause 4.2, will represent the contribution of all NEXT to the composite impairment noise of the test.

The PSD of this noise generator is one of the PSD profiles, defined in sub-clause 4.4. For testing upstream and downstream performance, different PSD profiles are to be used, as specified below.

**G1.UP.#** = X.LT.#  
**G1.DN.#** = X.NT.#

The symbols in this expression, refer to the following:

- Symbol “#” is a placeholder for noise model “A”, “B”, “C” or “D”.
- Symbol “X.LT.#” and “X.NT.#” refers to the self crosstalk profiles, as defined in 4.4

This PSD is not related to the cable because the cable portion is modelled separately as transfer function  $H_1(f,L)$ , as specified in sub-clause 4.2.

The noise of this noise generator shall be uncorrelated with all the other noise sources in the impairment generator, and uncorrelated with the xDSL system under test. The noise shall be random in nature and near Gaussian distributed, as specified in sub-clause 4.4.4.

### 4.3.2. Equivalent FEXT disturbance generator [G2.xx]

The FEXT noise generator represents the equivalent disturbance of all impairment that is identified as crosstalk noise from a predominantly Far End origin. This noise, filtered by the FEXT crosstalk coupling function of sub-clause 4.2, will represent the contribution of all FEXT to the composite impairment noise of the test.

The PSD of this noise generator is one of the PSD profiles, defined in sub-clause 4.4. For testing upstream and downstream performance, different PSD profiles are to be used, as specified below.

**G2.UP.#** = X.NT.#  
**G2.DN.#** = X.LT.#

The symbols in this expression, refer to the following:

- Symbol “#” is a placeholder for noise model “A”, “B”, “C” or “D”.
- Symbol “X.LT.#” and “X.NT.#” refers to the self crosstalk profiles, as defined in 4.4

This PSD is not related to the cable because the cable portion is modelled separately as transfer function  $H_2(f,L)$ , as specified in sub-clause 4.2.

The noise of this noise generator shall be uncorrelated with all the other noise sources in the impairment generator, and uncorrelated with the xDSL system under test. The noise shall be random in nature and near Gaussian distributed, as specified in sub-clause 4.4.4.

### 4.3.3. Background noise generator [G3]

The background noise generator is inactive and set to zero.

### 4.3.4. White noise generator [G4]

The white noise generator has a fixed, frequency independent value, and is set to -140 dBm/Hz into 135 Ω. The noise of this noise generator shall be uncorrelated with all the other noise sources in the impairment generator, and uncorrelated with the xDSL system under test. The noise shall be random in nature and near Gaussian distributed, as specified in sub-clause 4.4.4.

### 4.3.5. Broadcast RF noise generator [G5]

The broadcast RF noise generator represents the discrete tone-line interference caused by amplitude modulated broadcast transmissions in the SW, MW and LW bands which ingress into the differential or transmission mode of the wire-pair. These interference sources have more temporal stability than the amateur/ham interference because their carrier is not suppressed. The modulation index (MI) is usually up to 80%. These signals are detectable using a spectrum analyser and result in line spectra of varying amplitude in the frequency band of the xDSL system under test. Maximum observable power levels of up to -40 dBm (?) can occur on telephone lines in the distant vicinity of broadcast AM transmitters. The noise is typically dominated by the closest 10 or so transmitters to the victim wire-pair.

Several noise models are specified in this sub-clause. The average minimum power of each carrier frequency is specified in Table [\*] for each model.

[Ed. For further study. Its to be expected that the carrier frequencies below 1 MHz, as specified in the VDSL functional requirements, are suitable for SDSL too. Since the SDSL testloops are significantly longer than the VDSL testloops, its expected that the levels of these carrier frequencies must be higher than specified for VDSL.](#)

#### 4.3.6. Amateur RF noise generator [G6]

[Ed. Is there any need for this in the SDSL frequency band?..The associated carrier frequencies in the functional requirements for VDSL start at 1.8 MHz, which is far above the SDSL frequency band.](#)

#### 4.3.7. Impulse noise generator [G7]

A test with this noise generator is required to prove the implementation of the forward error correcting coder, which is specified to give some protection from impulsive noise. The impulse noise generator shall generate bursts of noise injected onto the line with sufficient power to ensure effective erasure of the data for the period of the burst.

Tests using this generator are to stress a FEC coder, currently specified as a RS block code with interleaving; there is no intention that the noise bursts are statistically representative of real noise. For realistic statistical models, see Annex C.

Two parameters are specified in this document, related to the length of the "on" and "off" state of the generated bursts. A third parameter is specified, related to their amplitude.

- T1 being the minimum length of isolated noise burst the coder shall always correct, and
- T2 being the maximum recovery time the coder shall need before it treats a succeeding noise burst as isolated from any predecessor burst.
- P<sub>b</sub> being the power level for the test noise bursts (see below) at which effective erasure of the data for the period of the burst is to be expected. (the bit error ratio during the burst should be approximately 0.5.)

Immunity shall be demonstrated on short and long loops, in the presence of noise to model cross-talk and RFI. The parameter values are specified in table 6. Further test details are given in sub-clause 5.

The impulse noise generator shall generate bursts of Additive White Gaussian Noise injected onto the line with power P<sub>b</sub>. Each noise burst shall be T1 long. The noise bursts shall be applied regularly with a spacing of T2.

T1	<TBD>	s
T2	1	s
P <sub>b</sub>	<TBD>	dBm

Table 6 : Definition of the impulse noise parameters

## 4.4. Profiles of the individual impairment generators

Crosstalk noise represents all impairment that originates from systems connected to adjacent wire pairs that are bundled in the same cable. Their wires are coupled to the wires of the xDSL system under test, causing this spectrum of crosstalk noise to vary with the electrical length of the testloop.

To simplify matters, the definition of crosstalk noise has been broken down into smaller, more easily specified components. The two generators G1 and G2 (see figure 11) represent the 'equivalent disturbance'. Their noise level originate from a mixture of many disturbers in a real scenario, as if all disturbers are colocated at the ends of the testloops.

This equivalent disturbance, filtered by the NEXT and FEXT coupling functions (see figure 11), will represent the crosstalk noise that is to be injected in the test setup. This approach has isolated their definition from the NEXT and FEXT coupling functions of the cable.

For xDSL testing, several models for crosstalk noise have been defined. The noise generated by these two equivalent disturbers is specified in this section in the frequency domain as well as in the time domain.

The frequency domain characteristics of each generator G1 and G2 is defined by a spectral profile, so each noise model has its own pair of spectral profiles.

- The profiles X.LT.# in this section describe the total *equivalent disturbance* of a technology mix that is virtually co-located at the LT end of the testloop. This noise is represented by equivalent disturbance generator G1, when stressing upstream signals, and by equivalent disturbance generator G2 when stressing downstream signals.
- The profiles X.NT.# in this section describe the total *equivalent disturbance* of a technology mix that is virtually co-located at the NT end of the testloop. This noise is represented by equivalent disturbance generator G2, when stressing upstream signals, and by equivalent disturbance generator G1 when stressing downstream signals.

Mark that the PSD levels of equivalent disturbance generator G1 and G2 are interchanged when changing upstream testing into downstream testing.

### 4.4.1. Frequency domain profiles for SDSL

This sub-clause specifies the PSD profiles X.LT.# and X.NT.# that apply for the equivalent disturbers G1 and G2 (see figure 11) when testing SDSL systems. In this nomenclature is "# used as a placeholder for noise model "A", "B", "C", and "D".

Four noise models have been defined for SDSL

- **Type "A" models** are intended to represent a *high penetration scenario* where the SDSL system under test is placed in a distribution cable (up to hundreds of wire pairs) that is filled with many other (potentially incompatible) transmission systems.
- **Type "B" models** are intended to represent a *medium penetration scenario* where the SDSL system under test is placed in a distribution cable (up to tens of wire pairs) that is filled with many other (potentially incompatible) transmission systems.
- **Type "C" models** are intended to represent a *legacy scenario* that accounts for systems such as ISDN-PRI (HDB3), in addition to the medium penetration scenario of model "B".
- **Type "D" models** are intended as *pure self-crosstalk scenario* to demonstrate the difference between a cable filled with SDSL only, or filled with a mixture of xDSL techniques.

The PSD profiles for each noise model are build up by a weighed sum of two individually defined profiles: self and alien crosstalk profiles.

$$\begin{aligned} X.LT.\# &= (X.S.LT.\# \diamond XA.LT.\#) \\ X.NT.\# &= (X.S.NT.\# \diamond XA.NT.\#) \end{aligned}$$

The symbols in this expression, refer to the following:

- Symbol "# is used as a placeholder for noise model "A", "B", "C" or "D".
- Symbol "X.S.LT.#" and "X.S.NT.#" refers to the self crosstalk profiles, as defined in 4.4.1.1.
- Symbol "X.A.LT.#" and "X.A.NT.#" refers to the alien crosstalk profiles, as defined in 4.4.1.2.

- Symbol “♦” refers to the FSAN crosstalk sum of two PSD’s. This FSAN crosstalk sum is defined as  $P_{\chi} = (P_{XS}^{K_n} + P_{XA}^{K_n})^{1/K_n}$ , where P denotes the PSD’s in W/Hz, and  $K_n=1/0.6$ . These profiles shall be met for all frequencies between 1 kHz to 1 MHz.

**4.4.1.1. Self crosstalk profiles**

The noise profiles XS.LT.# and XS.NT.#, representing the equivalent disturbance of self crosstalk, are implementation specific of the SDSL system under test. Transceiver manufacturers are left to determine these levels. For compliance with the requirements of this technical specification, the transceiver manufacturer shall determine the signal spectrum of the SDSL system under test, as it can be observed at the Tx port of the test set-up as described in sub clause 2.1. The measurement bandwidth for PSD shall be 1 kHz or less.

For testing SDSL, four noise models for self crosstalk have been defined. The LT- and NT-profiles are specified in table 7. In this nomenclature is “#” a placeholder for model “A”, “B”, “C” or “D”. “SDSL.dn” is the signal spectrum that SDSL transmits in downstream direction, and “SDSL.up” in upstream direction.

	Model A (XS.#.A)	Model B (XS.#.B)	Model C (XS.#.C)	Model D (XS.#.D)
XS.LT.#:	“SDSL.dn” + 11.7 dB	“SDSL.dn” + 7.1 dB	“SDSL.dn” + 7.1 dB	“SDSL.dn” + 10.1 dB
XS.NT.#:	“SDSL.up” + 11.7 dB	“SDSL.up” + 7.1 dB	“SDSL.up” + 7.1 dB	“SDSL.up” + 10.1 dB

**Table 7: Definition of the self crosstalk for SDSL testing. The different noise models use different Gain factors.**

**4.4.1.2. Alien crosstalk profiles**

The noise profiles XA.LT.# and XA.NT.#, representing the equivalent disturbance of alien crosstalk, are implementation specific of the SDSL system under test. For testing SDSL, four noise models for alien crosstalk have been defined, The LT-profiles are specified in table 8 and the NT-profiles in table 9. Each PSD profile originates from a mix of disturbers, as described in annex B. The alien noise in model D is made inactive, to achieve one pure self crosstalk scenario.

XA.LT.A	135 W	XA.LT.B	135 W	XA.LT.C	135 W	XA.LT.D	135 W
[Hz]	[dBm/Hz]	[Hz]	[dBm/Hz]	[Hz]	[dBm/Hz]	[Hz]	[dBm/Hz]

The PSD profiles are constructed with straight lines between these break frequencies, when plotted against a *logarithmic* frequency scale and a *linear* dBm scale. The levels are defined with into a 135W resistive load.**

#### 4.4.2. Frequency domain profiles for ADSL over POTS (E.C.)

This sub-clause specifies the PSD profiles X.LT.# and X.NT.# that apply for the equivalent disturbers G1 and G2 (see figure 11) when testing ADSL over POTS systems. In this nomenclature is “#” used as a placeholder for noise model “A”, “B”, “C”, and “D”.

Four noise models have been defined for ADSL over POTS.

- **Type “A” models** are intended to represent a *high penetration scenario* where the ADSL system under test is placed in a distribution cable (up to hundreds of wire pairs) that is filled with many other (potentially incompatible) transmission systems.
- **Type “B” models** are intended to represent a *medium penetration scenario* where the ADSL system under test is placed in a distribution cable (up to tens of wire pairs) that is filled with many other (potentially incompatible) transmission systems.
- **Type “C” models** are intended to represent a *legacy scenario* that accounts for systems such as ISDN-PRI (HDB3), in addition to the medium penetration scenario of model “B”.
- **Type “D” models** are intended as *pure self-crosstalk scenario* to demonstrate the difference between a cable filled with ADSL over POTS only, or filled with a mixture of xDSL techniques.

The LT-profiles are specified in table 10 and the NT-profiles in table 11. Each PSD profile originates from a mix of disturbers, as described in annex B.

These profiles shall be met for all frequencies between 1 kHz to 2 MHz.

X.LT.A [Hz]	135 W [dBm/Hz]	X.LT.B [Hz]	135 W [dBm/Hz]	X.LT.C [Hz]	135 W [dBm/Hz]	X.LT.D [Hz]	135 W [dBm/Hz]

Table 11: Break frequencies of the “X.NT.#” PSD masks that specify the equivalent disturbance for testing ADSL over POTS systems. The PSD profiles are constructed with straight lines between these break frequencies, when plotted against a *logarithmic* frequency scale and a *linear* dBm scale. The levels are defined with into a 135W resistive load.

**4.4.3. Frequency domain profiles for ADSL over ISDN (E.C.)**

This sub-clause specifies the PSD profiles X.LT.# and X.NT.# that apply for the equivalent disturbers G1 and G2 (see figure 11) when testing ADSL over ISDN systems. In this nomenclature is “#” used as a placeholder for noise model “A”, “B”, “C”, and “D”.

Four noise models have been defined for ADSL over ISDN:

- **Type “A” models** are intended to represent a *high penetration scenario* where the ADSL system under test is placed in a distribution cable (up to hundreds of wire pairs) that is filled with many other (potentially incompatible) transmission systems.
- **Type “B” models** are intended to represent a *medium penetration scenario* where the ADSL system under test is placed in a distribution cable (up to tens of wire pairs) that is filled with many other (potentially incompatible) transmission systems.
- **Type “C” models** are intended to represent a *legacy scenario* that accounts for systems such as ISDN-PRI (HDB3), in addition to the medium penetration scenario of model “B”.
- **Type “D” models** are intended as *pure self-crosstalk scenario* to demonstrate the difference between a cable filled with ADSL over POTS only, or filled with a mixture of xDSL techniques.

The LT-profiles are specified in table 12 and the NT-profiles in table 13. Each PSD profile originates from a mix of disturbers, as described in annex B.

These profiles shall be met for all frequencies between 1 kHz to 2 MHz.

#### 4.4.4. Time domain profiles of generator G1-G4

The noise, as specified in the frequency domain in sub-clause 4.3.1 to 4.3.4, shall be random in nature and near Gaussian distributed. This means that the amplitude distribution function of the combined impairment noise injected at the adding element (see figure 1) shall lie between the two boundaries as illustrated in figure 12 and defined in table 14.

The amplitude distribution function  $F(a)$  of noise  $u(t)$  is the fraction of the time that the absolute value of  $u(t)$  exceeds the value “a”. From this definition, it can be concluded that  $F(0) = 1$  and that  $F(a)$  monotonically decreases upto the point where “a” equals the peak value of the signal. From there on,  $F(a)$  vanishes:

$$F(a) = 0, \text{ for } a \geq |u_{peak}|.$$

The boundaries on the amplitude distribution ensure that the noise is characterised by peak values that are occasionally significantly higher than the rms-value of that noise (up to 5 times the rms-value).

Figure 12: Mask for the Amplitude Distribution Function: the non-shaded area is the allowed region. The boundaries of the mask are specified in Table 14.

Boundary ( $\sigma =$ rms value of noise)	interval	parameter	value
$F_{lower}(a) = (1 - \varepsilon) \cdot \{1 - erf((a/\sigma)/\sqrt{2})\}$	$0 \leq a/\sigma < CF$	crest factor	$CF = 5$
$F_{lower}(a) = 0$	$CF \leq a/\sigma < \infty$	gaussian gap	$\varepsilon = 0.1$
$F_{upper}(a) = (1 + \varepsilon) \cdot \{1 - erf((a/\sigma)/\sqrt{2})\}$	$0 \leq a/\sigma < A$		$A = CF/2 = 2.5$
$F_{upper}(a) = (1 + \varepsilon) \cdot \{1 - erf(A/\sqrt{2})\}$	$A \leq a/\sigma < \infty$		

Table 14: Upper and lower boundaries of the amplitude distribution function of the noise.

The meaning of the parameters in table 14 is as follows:

- CF denotes the minimum crest factor of the noise, that characterises the ratio between the absolute peak value and rms value ( $CF = |u_{peak}| / u_{rms}$ ).
- $\varepsilon$  denotes the gaussian gap that indicates how 'close' near gaussian noise approximates true gaussian noise.
- A denotes the point beyond which the upper limit is alleviated to allow the use of noise signals of practicable repetition length.

## 5. Transmission Performance tests

### 5.1. Bit error ratio requirements

The xDSL system under test shall operate with a noise margin of at least +6 dB and a long-term bit error ratio of  $< 1$  in  $10^7$  when operated over any of the test loops with the noise models and test conditions as specified in this clause.

The measurement period shall be at least 30 minutes. A long term performance test shall be performed for a period of not less than 24 hours to ensure long-term temporal stability (see sub-clause 5.3 and 5.4).

### 5.2. Measuring crosstalk noise margin

Before start-up of the xDSL modem under test, the level and shape of crosstalk noise is adjusted, while its level is probed at port Rx to meet the impairment level specification in sub-clause 4. This relative level is referred to as 0 dB. The transceiver link is subsequently activated, and the bit error ratio of the link is monitored.

For measuring the crosstalk margin, the crosstalk noise level of the impairment generator as defined in Tables 8 or 9, shall be increased by adjusting the gain of amplifier A1 in Figure 11, equally over the full frequency band of the xDSL system under test, until the bit error ratio is higher than  $10^{-7}$ . This BER will be achieved at an increase of noise of  $x$  dB, with a small uncertainty of  $\Delta x$  dB. This value  $x$  is defined as the crosstalk noise margin with respect to a standard noise model.

The noise margins shall be measured for upstream as well as downstream transmission under test loop #1, #2, #3, and #4.

There is at present no concept of amplitude margin for the noise bursts of generator G7.

### 5.3. Impulse noise testing

The impulse noise tests will be carried out in the presence of crosstalk noise, at the levels specified in sub-clause 4. The transceiver link is subsequently activated, and the bit error ratio of the link is monitored. The link shall have a BER less than  $10^{-7}$  for the duration of the test.

### 5.4. Upstream tests

Several xDSL performance tests shall be carried out to prove adequate upstream performance. These tests are specified in Table 15. Each symbolic name in this table refers to a specified noise model as defined in sub-clause 4. The injection of the impairment noise shall be at the LT side of the test-loop.

Test set	Class (code)	Loops	G1	G2	G3	G4	G5	G6	G7
U1		1-8	G1.UP.A	G2.UP.A	-	G4	G5	-	-
U2		4	G1.UP.A	G2.UP.A	-	G4	G5	-	G7

Table 15: Test matrix with composition of noise models in the upstream tests (for further study)

## 5.5. Downstream tests

Several xDSL performance tests shall be carried out to prove adequate downstream performance. These tests are specified in Table 16. Each symbolic name in this table refers to a specified noise model as defined in sub-clause 4. The injection of the impairment noise shall be at the NT side of the test-loop.

Test set	Class (code)	Loops	G1	G2	G3	G4	G5	G6	G7
D1		1-8	G1.DN.A	G2.DN.A	-	G4	G5	-	-
D2		2	G1.DN.A	G2.DN.A	-	G4	G5	-	G7
									-
									-
									-

Table 16: Test matrix with composition of noise models in the Downstream tests (for further study)

## 6. Micro interruptions

A micro interruption is a temporary line interruption due to external mechanical action on the copper wires constituting the transmission path, for example, at a cable splice. Splices can be hand-made wire-to-wire junctions, and during cable life oxidation phenomena and mechanical vibrations can induce micro interruptions at these critical points.

The effect of a micro interruption on the transmission system can be a failure of the digital transmission link, together with a failure of the power feeding (if provided) for the duration of the micro interruption.

The objective is that in the presence of a micro interruption of specified maximum length the xDSL transceiver should not reset, and the system should automatically reactivate.

The transceiver shall not be reset by a micro interruption event of duration  $t = 10$  ms which shall occur at an event frequency of 0,2 Hz.

[Ed. This whole issue is subject for further study.](#)

# Annex A [normative]: Line constants for the test loop-set

This appendix details the typical line constants for the cable sections in the testloops. The primary cable parameters vary with the frequency. Their typical values may be calculated at any frequency (up to a maximum frequency) by using empirical models.

## A.1. Transmission and reflection of (cascaded) sections

The testloops are defined by one or a cascade of cable sections. The characteristics of each section are specified by means of primary cable parameters  $\{Z_s, Y_p\}$  per unit length ( $L_0$ ); Some of these parameters are given in tabular form; others by means of an analytical expression. This sub clause summarizes how to evaluate the relevant characteristics of cable sections (s-parameters) from the primary parameters, and how evaluate these s-parameters for a cascade of cable sections.

Insertion loss and return loss of a cable section can be calculated from the primary parameters  $\{Z_s, Y_p\}$  per unit length ( $L_0$ ) by evaluating the two-port s-parameters, normalized to  $R_v = 135 \Omega$ .

$Z_{sx} = (L/L_0) \cdot Z_s$	$\gamma_x = \sqrt{Z_{sx} \cdot Y_{px}}$	$\alpha_x = \text{real}(\gamma_x)$	$R_{sx} = \text{real}(Z_{sx})$	$G_{px} = \text{real}(Y_{px})$
$Y_{sx} = (L/L_0) \cdot Y_s$	$Z_0 = \sqrt{Z_{sx} / Y_{px}}$	$\beta_x = \text{imag}(\gamma_x)$	$L_{sx} = \text{imag}(Z_{sx} / \omega)$	$C_{px} = \text{imag}(Y_{px} / \omega)$

$$S = \begin{bmatrix} S_{11} & S_{12} \\ S_{21} & S_{22} \end{bmatrix} = \frac{1}{(Z_0/R_v + R_v/Z_0) \cdot \tanh(\gamma_x) + 2} \times \begin{bmatrix} (Z_0/R_v - R_v/Z_0) \cdot \tanh(\gamma_x) & 2 / \cosh(\gamma_x) \\ 2 / \cosh(\gamma_x) & (Z_0/R_v - R_v/Z_0) \cdot \tanh(\gamma_x) \end{bmatrix}$$

insertion loss:  $1/S_{21}$   
return loss:  $1/S_{11}$

The s-parameters of two cable sections (a and b) in cascade can be calculated from the s-parameters  $S_a$  and  $S_b$  as described below:

$$S = \begin{bmatrix} S_{11} & S_{12} \\ S_{21} & S_{22} \end{bmatrix} = \frac{1}{1 - S_{22a} S_{11b}} \cdot \begin{bmatrix} S_{11a} - \Delta_{sa} S_{11b} & S_{12b} \cdot S_{12a} \\ S_{21a} \cdot S_{21b} & S_{22b} - \Delta_{sb} S_{22a} \end{bmatrix} \quad \Delta_s = S_{11} S_{22} - S_{12} S_{21}$$

## A.2. Cable sections for the SDSL test loops

The primary cable parameters  $Z_s = R_s + j\omega \cdot L_s$  and  $Y_p = 0 + j\omega \cdot C_p$  per unit length are specified for various frequencies in Table A.1 and A.2. They are based on existing RLCG tables specified for HDSL [\*], and extended up to 2 MHz. The values for frequencies in between are to be found by using a "cubic spline interpolation", as described in many textbooks, including [19].

## Annex B [informative]: Rationale behind the noise models

Various scenario's have been identified to be applied to xDSL testing. Each scenario is characterized in a technology mixture of different xDSL transmission systems. It is assumed that this mix is a fair representation of the technology mix in a multi-pair cable where the xDSL system under test is deployed.

For combining the individual disturbers into an *equivalent disturbance* of this mix, the FSAN noise combination method is used. The FSAN crosstalk sum for four individual PSD's is used for calculating the total equivalent disturbance of this technology mix. This sum equals for a mix of 4 technologies (P in W/Hz):

$$P = (P_1^{K_n} + P_2^{K_n} + P_3^{K_n} + P_4^{K_n})^{1/K_n}, \quad \text{at } K_n=1/0.6$$

The chosen technology mix is summarised below.

The noise models are based on the combined noise of different scenario's with xDSL systems.

### B.1 Technology mix of SDSL noise models

The PSD profiles of the equivalent disturbance for SDSL testing are based on the technology mix summarized below

- **Technology mix of model A (high penetration scenario)**

P <sub>0</sub>	SDSL	+ 11.7 dB (occupying about 90 wire pairs)
P <sub>1</sub>	ISDN/2B1Q	+ 11.7 dB (occupying about 90 wire pairs)
P <sub>2</sub>	HDSL/2B1Q (2-pair)	+ 9.6 dB (occupying about 40 wire pairs)
P <sub>3</sub>	ADSL over POTS	+ 11.7 dB (occupying about 90 wire pairs)
P <sub>4</sub>	ADSL over ISDN	+ 11.7 dB (occupying about 90 wire pairs)
  
- **Technology mix of model B (medium penetration scenario)**

P <sub>0</sub>	SDSL	+ 7.1 dB (occupying about 15 wire pairs)
P <sub>1</sub>	ISDN/2B1Q	+ 6.0 dB (occupying about 10 wire pairs)
P <sub>2</sub>	HDSL/2B1Q (2-pair)	+ 3.6 dB (occupying about 4 wire pairs)
P <sub>3</sub>	ADSL-lite	+ 6.0 dB (occupying about 10 wire pairs)
P <sub>4</sub>	ADSL over ISDN	+ 4.2 dB (occupying about 5 wire pairs)
  
- **Technology mix of model C ( legacy scenario)**

P <sub>0</sub>	SDSL	+ 7.1 dB (occupying about 15 wire pairs)
P <sub>1</sub>	ISDN/2B1Q	+ 6.0 dB (occupying about 10 wire pairs)
P <sub>2</sub>	HDSL/2B1Q (2-pair)	+ 3.6 dB (occupying about 4 wire pairs)
P <sub>3</sub>	ADSL-lite	+ 6.0 dB (occupying about 10 wire pairs)
P <sub>4</sub>	ADSL over ISDN	+ 4.2 dB (occupying about 5 wire pairs)
P <sub>5</sub>	ISDN-PRI/HDB3	+ 3.6 dB (occupying about 4 wire pairs)
  
- **Technology mix of model D (pure self-crosstalk scenario)**

P <sub>0</sub>	SDSL	+ 10.1 dB (occupying about 49 wire pairs)
----------------	------	---

**NOTE 1** These numbers are a compromise found between several telcos and they **do not** reflect the actual environment in one specific network.

**NOTE 2** The models approximate possible scenarios including ISDN/4B3T well enough. The difference of XA.LT.#, XA.NT.# between using ISDN/2B1Q and using ISDN/4B3T is negligible.

## B.2. Technology mix of ADSL noise models

The PSD profiles of the equivalent disturbance for ADSL testing are based on the technology mix summarized below

- **Technology mix of model A (high penetration scenario)**
  - P<sub>1</sub> ISDN/2B1Q + 11.7 dB (occupying about 90 wire pairs)
  - P<sub>2</sub> HDSL/2B1Q (2-pair) + 9.6 dB (occupying about 40 wire pairs)
  - P<sub>3</sub> ADSL (under test) + 13.5 dB (occupying about 180 wire pairs)
  - P<sub>4</sub> SDSL (2.3Mb/s) + 11.7 dB (occupying about 90 wire pairs)
  
- **Technology mix of model B (medium penetration scenario)**
  - P<sub>1</sub> ISDN/2B1Q + 6.0 dB (occupying about 10 wire pairs)
  - P<sub>2</sub> HDSL/2B1Q (2-pair) + 3.6 dB (occupying about 4 wire pairs)
  - P<sub>3</sub> ADSL (under test) + 7.1 dB (occupying about 15 wire pairs)
  - P<sub>4</sub> SDSL (2.3Mb/s) + 7.1 dB (occupying about 15 wire pairs)
  
- **Technology mix of model C (legacy scenario)**
  - P<sub>1</sub> ISDN/2B1Q + 6.0 dB (occupying about 10 wire pairs)
  - P<sub>2</sub> HDSL/2B1Q (2-pair) + 3.6 dB (occupying about 4 wire pairs)
  - P<sub>3</sub> ADSL (under test) + 7.1 dB (occupying about 15 wire pairs)
  - P<sub>4</sub> SDSL (2.3Mb/s) + 7.1 dB (occupying about 15 wire pairs)
  - P<sub>5</sub> ISDN-PRI/HDB3 + 3.6 dB (occupying about 4 wire pairs)
  
- **Technology mix of model D (pure self-crosstalk scenario)**
  - P<sub>1</sub> ADSL (under test) + 10.1 dB (occupying about 49 wire pairs)

**NOTE 1** These numbers are a compromise found between several telcos and they **do not** reflect the actual environment in one specific network.

**NOTE 2** The models approximate possible scenarios including ISDN/4B3T well enough. The difference of noise X.LT.#, X.NT.# between using ISDN/2B1Q and using ISDN/4B3T is negligible.

**NOTE 3** The technology "ADSL" in this mix is "ADSL over POTS" when ADSL over POTS is tested, and "ADSL over ISDN: when ADSL over ISDN is tested.

## B.3. Assumptions on individual PSDs

The individual systems in this technology mix can be described by simplified PSD masks, and the break frequencies of these masks are summarised in table 17 and 19. The PSD masks in table 17 are constructed with straight lines between these break frequencies, when plotted against a *logarithmic* frequency scale and a *linear* dBm scale.

<sup>1</sup> This ISDN/3B4T PSD is based on the **mask** that is specified in ETSI standards, and not on a **template** for the expected average value. Using this PSD for performance simulation purposes may therefore cause results that are a bit pessimistic. This has no consequences to the ADSL noise models, since the ISDN/3B4T PSD is not used here. An update of this PSD, for simulation purposes in general, is for further study.

Table 17: Break frequencies of the PSD masks of individual transmission systems. ADSL over ISDN refers to the case of ISDN-2B1Q. For reasons of simplicity, the brick walls at 4 kHz are modelled as step between 3.99 kHz to 4 kHz. Note that the PSD's of ISDN-BA (4B3T) and HDSL/2 (CAP) are included here for completeness, but are not used to calculate the noise models.

$$P(f) = \frac{2}{f_{sym}} \cdot \frac{\text{sinc}^2(f/f_{sym})}{1 + (f/f_{3dB})^{2 \cdot N}} \cdot K_N^2 \cdot P_0 \quad [W/Hz]$$

$P_0 = 14.5 \text{ dBm} \approx 28.18 \text{ mW}; R_s=135 \Omega;$   
 $f_{sym} = 2.312/3 \text{ MHz}; f_{3dB} = f_{sym}/2; N=6; K_N = 1.14$   
 $\text{sinc}(x) = \sin(\pi \cdot x) / (\pi \cdot x)$

Table 18: PSD mask of the SDSL system, as a function of the frequency. (assuming 2.304 kb/s datarate, 8kb/s overhead, 3 bits per symbol)

$$P(f) = \frac{2}{f_{sym}} \cdot \frac{\text{sinc}^2(f/f_{sym}-1)}{1 + (f/f_{3dB})^{2 \cdot N}} \cdot P_0 \quad [W/Hz]$$

$P_0 = 12.4 \text{ mW} = 10.92 \text{ dBm}; R_s=130 \Omega;$   
 $f_{sym} = 1.024 \text{ MHz}; f_{3dB} = f_{sym}; N=0.9$   
 $\text{sinc}(x) = \sin(\pi \cdot x) / (\pi \cdot x)$

Table 19: PSD mask of the ISDN-PRI (HDB3) system, as a function of the frequency.

The PSD levels, of the sources in table 17 and 19, are defined, when terminated by their associated source impedances  $R_s$ . The calculated noise models take account for the (minor) power drop caused by the fact that the interfering systems are not terminated with their nominal source impedance. They are all terminated with the cable impedance. The corresponding correction factor is calculated as follows:

Let  $P_V$  be the output power spectral density of these sources when terminated with the normalized test impedance  $R_V$ , level  $P_s$  when terminated with the source impedance  $R_s$ , and level  $P$  when terminated by the cable impedance. Calculating the output level of a source with impedance  $R_s$  by the normalized test impedance  $R_V$  requires the following correction in the output level to their nominal level:

$$P_V = \left( 2 \cdot \frac{\sqrt{R_V \cdot R_s}}{R_V + R_s} \right)^2 \times P_s$$

Terminating a 150Ω system by 135Ω requires -0.0120 dB correction in  $P_s$ .  
Terminating a 135Ω system by 135Ω requires -0.0000 dB correction in  $P_s$ .

Terminating a 120Ω system by 135Ω requires -0.0151 dB correction in  $P_s$ .  
Terminating a 110Ω system by 135Ω requires -0.0455 dB correction in  $P_s$ .  
Terminating a 100Ω system by 135Ω requires -0.0974 dB correction in  $P_s$ .

In a real access network, this correction is slightly different, because the systems are terminated with the cable impedance in stead of the normalized test impedance  $R_V$ . For reasons of simplicity, (all cables are different in impedance), the noise models are based on the simplification that all interfering systems are terminated with the normalized test impedance  $R_V=135\Omega$ .

## Annex C [informative]: Realistic Impulsive noise models

In the body of this document, tests are described which test the implementation of measures to suppress impulsive noise (see sub-clause 4.3.7). For practical reasons a standards test cannot use a realistic representation of impulsive noise for this purpose.

This appendix is concerned with impulsive noise and its realistic representation, for use in simulation and emulation. Simulations will typically be used by modem designers to determine the suppression measures to be implemented. Emulation will typically be used by telcos to estimate a modem's performance in a real network.

### C.1. Noise Model

[Ed. This whole issue is the subject of ongoing study. See also TD18/19/20/21 from Edinburgh](#)
