Intellectual Property Rights

IPRs essential or potentially essential to the present document may have been declared to ETSI. The information pertaining to these essential IPRs, if any, is publicly available for **ETSI members and non-members**, and can be found in ETSI SR 000 314: "*Intellectual Property Rights (IPRs); Essential, or potentially Essential, IPRs notified to ETSI in respect of ETSI standards*", which is available from the ETSI Secretariat. Latest updates are available on the ETSI Web server (<http://webapp.etsi.org/IPR/home.asp>).

Pursuant to the ETSI IPR Policy, no investigation, including IPR searches, has been carried out by ETSI. No guarantee can be given as to the existence of other IPRs not referenced in ETSI SR 000 314 (or the updates on the ETSI Web server) which are, or may be, or may become, essential to the present document.

Foreword

This Technical Report (TR) has been produced by ETSI Technical Committee Transmission and Multiplexing (TM).

The present document is part 2 of a multi-part deliverable covering Transmission and Multiplexing (TM); Access networks; Spectral management on metallic access networks, as identified below:

Part 1: "Definitions and signal library";

Part 2: "Technical methods for performance evaluations";

1 Scope

The present document gives guidance on a common methodology for studying the impact of noise on xDSL performance (maximum reach, noise margin, maximum bitrate) when changing parameters within various Spectral Management scenarios. These methods enable reproducible results and a consistent presentation of the assumed conditions (characteristics of cables and xDSL equipment) and configuration (chosen technology mixture and cable fill) of each scenario.

The technical methods include computer models for estimating:

- xDSL receiver capability of detecting signals under noisy conditions;
- xDSL transmitter characteristics;
- cable characteristics;
- crosstalk cumulation in cables, originating from a mix of xDSL disturbers.

The objective is to provide the technical means for evaluating the performance of xDSL equipment within a chosen scenario. This includes the description of performance properties of equipment.

Another objective is to assist the reader with applying this methodology by providing examples on how to specify the configuration and the conditions of a scenario in an unambiguous way. The distinction is that a configuration of a scenario can be controlled by access rules while the conditions of a scenario cannot.

Possible applications of the present document include:

- Studying access rules, for the purpose of bounding the crosstalk in unbundled networks.
- Studying deployment rules, for the various systems present in the access network.
- Studying the impact of crosstalk on various technologies within different scenarios.

The scope of the present document is explicitly restricted to the methodology for defining scenarios and quantifying the performance of equipment within such a scenario. All judgement on what access rules are required, what performance is acceptable, or what combinations are spectral compatible, is explicitly beyond the scope of the present document. The same applies for how realistic the example scenarios are.

The models in the present document are not intended to set requirements for DSL equipment. These requirements are contained in the relevant transceiver specifications. The models in the present document are intended to provide a reasonable estimate of real-world performance but may not include every aspect of modem behaviour in real networks. Therefore real-world performance may not accurately match performance numbers calculated with these models.

3 Definitions and abbreviations

3.1 Definitions

For the purposes of the present document, the following terms and definitions apply:

access port: is the physical location, appointed by the loop provider, where signals (for transmission purposes) are injected into the local loop wiring

access rule: mandatory rule for achieving access to the local loop wiring, equal for all network operators who are making use of the same network cable that bounds the crosstalk in that network cable

cable fill (or degree of penetration): number and mixture of transmission techniques connected to the ports of a binder or cable bundle that are injecting signals into the access ports

Cable Management Plan (CMP): list of selected access rules dedicated to a specific network

NOTE: This list may include associated descriptions and explanations.

deployment rule: voluntary rule, irrelevant for achieving access to the local loop wiring and proprietary to each individual network operator

NOTE: A deployment rule reflects a network operator's own view about what the maximum length or maximum bitrate may be for offering a specific transmission service to ensure a chosen minimum quality of service.

disturber: source of interference in spectral management studies coupled to the wire pair connecting victim modems

NOTE: This term is intended solely as a technical term, defined within the context of these studies, and is not intended to imply any negative judgement.

downstream transmission: transmission direction from port, labelled as LT-port, to a port, labelled as NT-port

NOTE: This direction is usually from the central office side via the local loop wiring, to the customer premises.

Echo Cancelled (EC): term used within the context of ADSL to designate ADSL systems with spectral overlap of downstream and upstream signals

NOTE: In this context, the usage of the abbreviation "EC" was only kept for historical reasons. The usage of the echo cancelling technology is not only limited to spectrally overlapped systems, but can also be used by FDD systems.

local loop wiring: part of a metallic access network, terminated by well-defined ports, for transporting signals over a distance of interest

NOTE: This part includes mainly cables, but may also include a Main Distribution Frame (MDF), street cabinets, and other distribution elements. The local loop wiring is usually passive only, but may include active splitter-filters as well.

loop provider: organization facilitating access to the local loop wiring

NOTE: In several cases the loop provider is historically connected to the incumbent network operator, but other companies may serve as loop provider as well.

LT-access port (or LT-port for short): is an access port for injecting signals, designated as "LT-port"

NOTE: Such a port is commonly located at the central office side, and intended for injecting "downstream" signals.

max data rate: maximum data rate that can be recovered according to predefined quality criteria, when the received noise is increased with a chosen noise margin (or the received signal is decreased with a chosen signal margin)

network operator: organization that makes use of a local loop wiring for transporting telecommunication services

NOTE: This definition covers incumbent as well as competitive network operators.

noise margin: ratio (P_{n2}/P_{n1}) by which the received noise power P_{n1} may increase to power P_{n2} until the recovered signal no longer meets the predefined quality criteria

NOTE: This ratio is commonly expressed in dB.

NT-access port (or NT-port for short): is an access port for injecting signals, designated as "NT-port"

NOTE: Such a port is commonly located at the customer premises, and intended for injecting "upstream" signals.

performance: is a measure of how well a transmission system fulfils defined criteria under specified conditions

NOTE: Such criteria include reach, bitrate and noise margin.

power back-off: is a generic mechanism to reduce the transmitter's output power

NOTE: It has many purposes, including the reduction of power consumption, receiver dynamic range, crosstalk, etc.

power cut-back: specific variant of power back-off, used to reduce the dynamic range of the receiver, that is characterized by a frequency independent reduction of the in-band PSD

NOTE: It is used, for instance, in ADSL and SDSL.

PSD mask: absolute upper bound of a PSD, measured within a specified resolution band

NOTE: The purpose of PSD masks is usually to specify maximum PSD levels for stationary signals.

PSD template: expected average PSD of a stationary signal

NOTE: The purpose of PSD templates is usually to perform simulations. The levels are usually below or equal to the associated PSD masks.

signal category: is a class of signals meeting the minimum set of specifications identified in TR 101 830-1 [1]

NOTE: Some signal categories may distinct between different sub-classes, and may label them for instance as signals for "downstream" or for "upstream" purposes.

signal margin: ratio (P_{s1}/P_{s2}) by which the received signal power P_{s1} may decrease to power P_{s2} until the recovered signal no longer meets the predefined quality criteria

NOTE: This ratio is commonly expressed in dB.

spectral compatibility: generic term for the capability of transmission systems to operate in the same cable

NOTE: The precise definition is application dependent and has to be defined for each group of applications.

spectral management: art of making optimal use of limited capacity in (metallic) access networks

NOTE: This is for the purpose of achieving the highest reliable transmission performance and includes:

- § Designing of deployment rules and their application.
- § Designing of effective access rules.
- § Optimized allocation of resources in the access network, e.g. access ports, diversity of systems between cable bundles, etc.
- § Forecasting of noise levels for fine-tuning the deployment.
- § Spectral policing to enforce compliance with access rules.
- § Making a balance between conservative and aggressive deployment (low or high failure risk).

spectral management rule: generic term, incorporating (voluntary) deployment rules, (mandatory) access rules and all other (voluntary) measures to maximize the use of local loop wiring for transmission purposes

transmission equipment: equipment connected to the local loop wiring that uses a transmission technique to transport information

transmission system: set of transmission equipment that enables information to be transmitted over some distance between two or more points

transmission technique: electrical technique used for the transportation of information over electrical wiring

upstream transmission: transmission direction from a port, labelled as NT-port, to a port, labelled as LT-port

NOTE: This direction is usually from the customer premises, via the local loop wiring, to the central office side.

victim modem: modem, subjected to interference (such as crosstalk from all other modems connected to other wire pairs in the same cable) that is being studied in a spectral management analysis

NOTE: This term is intended solely as a technical term, defined within the context of these studies, and is not intended to imply any negative judgement.

3.2 Abbreviations

For the purposes of the present document, the following abbreviations apply:

2B1Q	2-Binary, 1-Quaternary (Use of 4-level PAM to carry two bits per pulse)
ADSL	Asymmetric Digital Subscriber Line
BER	Bit Error Ratio
CAP	Carrier less Amplitude/Phase modulation
CMP	Cable Management Plan
DFE	Decision Feedback Equalizer
DMT	Discrete MultiTone modulation
EC	Echo Cancelled
EPL	Estimated Power Loss
FBL	Fractional Bit Loading
FDD	Frequency Division Duplexing/Duplexed
FSAN	Full Service Access Network
GABL	Gain Adjusted Bit Loading
HDSL	High bitrate Digital Subscriber Line
ISDN	Integrated Services Digital Network
LT-port	Line Termination - port (<i>commonly at central office side</i>)
LTU	Line Termination Unit
MDF	Main Distribution Frame
NT-port	Network Termination - port (<i>commonly at customer side</i>)
NTU	Network Termination Unit
PAM	Pulse Amplitude Modulation
PBO	Power Back-Off
PSD	Power Spectral Density (single sided)
QAM	Quadrature Amplitude Modulation
RBL	Rounded Bit Loading
SDSL	Symmetrical (single pair high bitrate) Digital Subscriber Line
SNR	Signal to Noise Ratio (<i>ratio of powers</i>)
TBL	Truncated Bit Loading
TRA	TRAnsmitter
UC	Ungerboeck Coded (also known as trellis coded)
VDSL	Very-high-speed Digital Subscriber Line
xDSL	(all systems) Digital Subscriber Line

4 Transmitter signal models for xDSL

A transmitter model in this clause is mainly a PSD description of the transmitted signal under matched conditions, plus an output impedance description to cover mismatched conditions as well.

PSD *masks* of transmitted xDSL signals are specified in several documents for various purposes, for instance in TR 101 830-1 [1]. These PSD masks, however, cannot be applied directly to the description of a transmitter model. One reason is that masks are specifying an upper limit, and not the expected (averaged) values. Another reason is that the definition of the true PSD of a time-limited signal requires no resolution bandwidth at all (it is defined by means of an autocorrelation, followed by a Fourier transform) while PSD *masks* do rely on some resolution bandwidth. They describe values that are (slightly) different from the true PSD; especially at steep edges (e.g. guard bands), and for modelling purposes this difference is sometimes very relevant.

To differentiate between several PSD descriptions, *masks* and *templates* of a PSD are given a different meaning. Masks are intended for proving compliance to standard requirements, while templates are intended for modelling purposes. This clause summarize various xDSL transmitter models, by defining *template* spectra of output signals.

In some cases, models are marked as "default" and/or as "alternative". Both models are applicable, but in case a preference of either of them does not exist, the use of the "default" models is recommended. Other (alternative) models may apply as well, provided that they are specified.

4.1 Generic transmitter signal model

A generic model of an xDSL transmitter is essentially a linear signal source. The Thevenin equivalent of such a source equals an ideal voltage source U_s having a real resistor R_s in series. The output voltage of this source is random in nature (as a function of the time), and occupies a relatively broad spectrum. Correlation between transmitters is taken to be negligible. The autocorrelation properties of a transmitter's signal are taken to be adequately represented by a PSD template.

This generic model can be made specific by defining:

- The output impedance R_s of the transmitter.
- The template of the PSD, measured at the output port, when terminated with an external impedance equal to R_s . This is identified as the "matched condition", and under this condition the output power equals the maximum power that is available from this source. Under all other (mis-matched) termination conditions the output power will be lower.

4.2 Transmitter signal model for "ISDN.2B1Q"

The PSD template for modelling the "ISDN.2B1Q" transmit spectrum is defined by the theoretical sinc-shape of PAM encoded signals, with additional filtering and with a noise floor. The PSD is the maximum of both power density curves, as summarized in expression 1 and the associated table 1. The coefficient q_N scales the total signal power of $P_1(f)$ to a value that equals P_{ISDN} . This value is dedicated to the used filter characteristics, but equals $q_N=1$ when no filtering is applied ($f_L \rightarrow 0, f_H \rightarrow \infty$). The source impedance equals 135 Ω .

$P_1(f) = P_{ISDN} \times \frac{2 \times q_N}{f_X} \times \text{sinc}^2\left(\frac{f}{f_X}\right) \times \frac{1}{1 + \left(\frac{f}{f_H}\right)^{2 \cdot N_H}} \times \frac{1}{1 + \left(\frac{f_L}{f}\right)^2} \quad [W / Hz]$
$P_2(f) = \frac{10^{(P_{floor_dBm}/10)}}{1000} \quad [W / Hz]$
$P(f) = \max(P_1(f), P_2(f)) \quad [W / Hz]$
<p>Where:</p> $P_{ISDN} = \left(10^{P_{ISDN_dBm}/10}\right) / 1000 \quad [W]$ $R_S = 135 \quad [\Omega]$ $\text{sinc}(x) = \sin(\pi \cdot x) / (\pi \cdot x)$ <p><i>Default values for remaining parameters are summarized in table 1.</i></p>

Expression 1: PSD template for modelling "ISDN.2B1Q" signals

Different ISDN implementations, may use different filter characteristics, and noise floor values. Table 1 specifies *default* values for ISDN implementations, in the case where 2nd order Butterworth filtering has been applied. The default noise floor equals the maximum PSD level that meets the out-of-band specification of the ISDN standard (TS 102 080 [3]).

Table 1: Default parameter values for the ISDN.2B1Q templates, as defined in expression 1 - These default values are based on 2nd order Butterworth filtering

Type	f_X [kHz]	f_H [kHz]	f_L [kHz]	N_H	q_N	P_{ISDN_dBm} [dBm]	P_{floor_dBm} [dBm/Hz]
ISDN.2B1Q	80	$1 \times f_X$	0	2	1,1257	13,5	-120

4.3 Transmitter signal model for "ISDN.2B1Q/filtered"

When ISDN signals have to pass a low-pass filter (such as in an ADSL splitter) before they reach the line, the disturbance caused by these ISDN systems to other wire pairs will change, as well as their performance. SpM studies should therefore make a distinction between crosstalk generated from ISDN systems connected directly to the line and filtered ISDN systems.

The PSD template for modelling a "ISDN.2B1Q/filtered" transmitter signal that has passed a low-pass splitter/filter, is defined in table 2 in terms of break frequencies. It has been constructed from the transmitter PSD template, filtered by the low-pass transfer function representing the splitter/filter.

The values are based on filter assumptions according to splitter specifications in TS 101 952-1-3 [14] and TS 101 952-1-4 [15]. The associated values are constructed with straight lines between these break frequencies, when plotted against a *logarithmic* frequency scale and a *linear* dBm scale.

Table 2: PSD template for modelling "ISDN.2B1Q/filtered" signals

ISDN.2B1Q/filtered	(135W)
f [Hz]	P [dBm/Hz]
1 k	-32,1
10 k	-32,3
20 k	-33,1
30 k	-34,5
40 k	-36,6
50 k	-39,8
60 k	-44,5

190 k	-135,2
200 k	-135,8
210 k	-137,8
220 k	-140,0
30 M	-140,0

4.4 Line-shared signal model for "ISDN.2B1Q"

The PSD template for modelling the line-shared signal from an ISDN.2B1Q transmitter that has passed the low-pass and the high-pass part of a splitter/filter for sharing the line with ADSL signals, is defined in table 3 in terms of break frequencies. It has been constructed from the transmitter PSD template, filtered by the low-pass and the high-pass transfer function representing the splitter/filter.

The values are based on filter assumptions according to splitter specifications in TS 101 952-1-3 [14] and in TS 101 952-1-4 [15]. The associated values are constructed with straight lines between these break frequencies, when plotted against a *logarithmic* frequency scale and a *linear* dBm scale.

Table 3: PSD template for modelling line shared "ISDN.2B1Q" signals

Line-shared ISDN.2B1Q	(135W)
f [Hz]	P [dBm/Hz]
1 k	-40,1
10 k	-40,3

4.5 Transmitter signal model for "ISDN.MMS43"

The PSD template for modelling the "ISDN.MMS43" transmit spectrum (also known as ISDN.4B3T) is defined by a combination of a theoretical curve and a noise floor. The PSD is the maximum of both power density curves, as summarized in expression 2. The source impedance equals 150 Ω .

$P_1(f) = P_{ISDN} \times \frac{2}{f_0} \times \left[\text{sinc}^2\left(\frac{f}{f_0}\right) + \text{sinc}^2\left(\frac{f - f_{P1}}{f_0}\right) + \text{sinc}^2\left(\frac{f - f_{P2}}{f_0}\right) \right] \times \frac{1}{1 + \left(\frac{f}{f_{L1}}\right)^4} \times \frac{1}{1 + \left(\frac{f}{f_{L2}}\right)^4} \quad [W / Hz]$
$P(f) = P_1(f) + P_{floor} \quad [W / Hz]$
<p>Where:</p> $P_{ISDN} = \left(10^{P_{ISDN_dBm}/10}\right) / 1000 \quad [W], \quad P_{ISDN_dBm} = 13,5 \text{ dBm}$ $P_{floor} = \left(10^{P_{floor_dBm}/10}\right) / 1000 \quad [W/Hz], \quad P_{floor_dBm} = -125 \text{ dBm/Hz}$ $f_0 = 120 \text{ kHz}; \quad f_{P1} = 1020 \text{ kHz}; \quad f_{P2} = 1860 \text{ kHz}; \quad f_{L1} = 80 \text{ kHz}; \quad f_{L2} = 1020 \text{ kHz};$ $\text{sinc}(x) = \sin(\pi \cdot x) / (\pi \cdot x)$

Expression 2: PSD template for modelling "ISDN.MMS43" signals

4.6 Transmitter signal model for "ISDN.MMS43/filtered"

When ISDN signals have to pass a low-pass filter (such as in an ADSL splitter) before they reach the line, the disturbance caused by these ISDN systems to other wire pairs will change, as well as their performance. SpM studies should therefore make a distinction between crosstalk generated from ISDN systems connected directly to the line and filtered ISDN systems.

The PSD template for modelling a "ISDN.MMS43/filtered" transmitter signal that has passed a low-pass splitter/filter, is defined in table 4 in terms of break frequencies. It has been constructed from the transmitter PSD template, filtered by the low-pass transfer function representing the splitter/filter.

The values are based on filter assumptions according to splitter specifications in TS 101 952-1-3 [14] and in TS 101 952-1-4 [15]. The associated values are constructed with straight lines between these break frequencies, when plotted against a *logarithmic* frequency scale and a *linear* dBm scale.

Table 4: PSD template for modelling "ISDN.MMS.43/filtered" signals

ISDN.MMS.43/filtered	(150 W)
f [Hz]	P [dBm/Hz]
1 k	-34,5

4.7 Line-shared signal model for "ISDN.MMS43"

The PSD template for modelling the line-shared signal from an ISDN.MMS43 transmitter (also known as vv ISDN.4B3T), that has passed the low-pass and the high-pass part of a splitter/filter for sharing the line with ADSL signals, is defined in table 5 in terms of break frequencies. It has been constructed from the transmitter PSD template, filtered by the low-pass and the high-pass transfer function representing the splitter/filter.

The values are based on filter assumptions according to splitter specifications in TS 101 952-1-3 [14] and in TS 101 952-1-4 [15]. The associated values are constructed with straight lines between these break frequencies, when plotted against a *logarithmic* frequency scale and a *linear* dBm scale.

Table 5: PSD template for modelling line shared "ISDN.MMS.43" signals

Line-shared ISDN.MMS.43	(150 W)

4.8 Transmitter signal model for "HDSL.2B1Q"

The PSD templates for modelling the spectra of various "HDSL.2B1Q" transmitters are defined by the theoretical sinc-shape of PAM encoded signals, with additional filtering and a noise floor. The PSD template is the maximum of both power density curves, as summarized in expression 3 and associated table 6.

The coefficient q_N scales the total signal power of $P_1(f)$ to a value that equals P_0 . This value is dedicated to the filter characteristics used, but equals $q_N=1$ when no filtering is applied ($f_L \rightarrow 0, f_H \rightarrow \infty$). The source impedance equals 135 Ω .

$$P_1(f) = P_{HDSL} \times \frac{2 \times q_N}{f_X} \times \text{sinc}^2\left(\frac{f}{f_X}\right) \times \frac{1}{1 + \left(\frac{f_L}{f}\right)^2} \times \frac{1}{1 + \left(\frac{f}{f_{H1}}\right)^{2 \cdot N_{H1}}} \times \frac{1}{1 + \left(\frac{f}{f_{H2}}\right)^{2 \cdot N_{H2}}} \quad [W / Hz]$$

$$P_2(f) = \frac{10^{(P_{\text{floor_dBm}}/10)}}{1000} \quad [W / Hz]$$

$$P(f) = \max(P_1(f), P_2(f)) \quad [W / Hz]$$

Where:

$$P_{HDSL} = \left(10^{P_{HDSL_dBm}/10}\right) / 1000 \quad [W]$$

$$R_S = 135 \quad [\Omega]$$

$$\text{sinc}(x) = \sin(\pi \cdot x) / (\pi \cdot x)$$

Default values for remaining parameters are summarized in table 6.

Expression 3: PSD template for modelling "HDSL.2B1Q" signals

Different HDSL implementations, may use different filter characteristics, and noise floor values. Table 6 summarizes *default* values for modelling HDSL transmitters (name starting with a "D"), as well as *alternative* values (name starting with an "A"). The power level P_{HDSL} equals the maximum power allowed by the HDSL standard (TS 101 135 [4]), since a nominal value does not exist in that standard. The noise floor P_{floor} equals a value observed for various implementations of HDSL.2B1Q/2, and assumed to be valid for other HDSL.2B1Q variants too.

Table 6: Parameter values for the HDSL.2B1Q templates, as defined in expression 3

Model	Type	f_x kHz	f_L kHz	f_{H1}	N_{H1}	f_{H2}	N_{H2}	q_N	$P_{\text{HDSL_dBm}}$ dBm	$P_{\text{floor_dBm}}$ dBm/Hz
D1	HDSL.2B1Q/1	1 160	3	$0,42 \times f_x$	3	N/A	N/A	1,4662	14	-133
D2	HDSL.2B1Q/2	584	3	$0,68 \times f_x$	4	N/A	N/A	1,1915	14	-133
A2.1	HDSL.2B1Q/2	584	3	$0,50 \times f_x$	3	N/A	N/A	1,3501	14	-133
A2.2	HDSL.2B1Q/2	584	3	$0,68 \times f_x$	4	$1,50 \times f_x$	2	1,1965	14	-133
D3	HDSL.2B1Q/3	392	3	$0,50 \times f_x$	3	N/A	N/A	1,3642	14	-133
NOTE: The alternative values are based on higher order Butterworth filtering. Choose $f_{H2=\infty}$ and $N_{H2}=1$ when not applicable (N/A).										

NOTE: Model A2.1 assumes a minimum amount of filtering that is required to meet the transmit specifications in TS 101 135 [4]. Model D2 outperforms these transmit requirements by assuming the application of higher order filtering. Nevertheless, model D2 is identified as a "default" model, instead of A2.1, because it has been demonstrated that several commonly used chipsets have implemented this additional filtering. When spectral compatibility studies show that model D2 is significantly friendlier to other systems in the cable than model A2.1, it is recommended to verify that model D2 is adequate for de HDSL modem under study.

4.9 Transmitter signal model for "HDSL.CAP"

The PSD templates for modelling signals generated by HDSL.CAP transmitters are different for single-pair and two-pair HDSL systems. The PSD templates for modelling the "HDSL.CAP/1" transmit spectra for one-pair systems and "HDSL.CAP/2" transmit spectra for two-pair systems are defined in terms of break frequencies, as summarized in table 7. These templates are taken from the nominal shape of the transmit signal spectra, as specified in the ETSI HDSL standard (TS 101 135 [4]).

The associated values are constructed with straight lines between these break frequencies, when plotted against a *logarithmic* frequency scale and a *linear* dBm scale. The source impedance equals $R_s = 135 \Omega$.

Table 7: PSD template values at break frequencies for modelling "HDSL.CAP"

HDSL.CAP/1		HDSL.CAP/2	
1-pair 135 W		2-pair 135 W	
[Hz]	[dBm/Hz]	[Hz]	[dBm/Hz]
1	-57	1	-57
4,0 k	-57	3,98 k	-57
33 k	-43	21,5 k	-43
62 k	-40	39,02 k	-40
390,67 k	-40	237,58 k	-40
419,67 k	-43	255,10 k	-43
448,67 k	-60	272,62 k	-60
489,02 k	-70	297,00 k	-70
1 956,08 k	-120	1,188 M	-120
30 M	-120	30 M	-120
NOTE: The out-of-band values may be lower than specified in these models.			

4.10 Transmitter signal model for "SDSL"

The PSD templates for modelling the spectra of "SDSL" transmitters are defined by the theoretical sinc-shape of PAM encoded signals, plus additional filtering and a noise floor. The transmit spectrum is defined as summarized in expression 4 and the associated table 8.

NOTE: These models are applicable to SDSL 16-UC-PAM at rates up to 2,312 Mb/s.

This PSD template is taken from the nominal shape of the transmit signal spectrum, as specified in the ETSI SDSL standard (TS 101 524 [5]). The source impedance equals $R_s=135 \Omega$.

$P_{sinc}(f) = \frac{K_{sdsl}}{R_s \times f_x} \times \text{sinc}^2\left(\frac{f}{f_x}\right) \times \frac{1}{1 + \left(\frac{f}{f_H}\right)^{2 \cdot N_H}} \times \frac{1}{1 + \left(\frac{f_L}{f}\right)^2} \quad [W / Hz]$
$P_{floor}(f) = \frac{10^{(P_{floor_dBm}/10)}}{1000} \quad [W / Hz]$
$P_{SDSL}(f) = P_{sinc} + P_{floor} \quad [W / Hz]$
$R_s = 135 \Omega$ $P_{floor} = -120 \text{ dBm/Hz}$ $\text{sinc}(x) = \sin(\pi \cdot x) / (\pi \cdot x)$ <i>Parameter values are defined in table 8</i>

Expression 4: PSD template values for modelling both the symmetric and asymmetric modes of SDSL

Table 8: Parameter values for the SDSL templates, as defined in expression 4

Mode	Data Rate R [kb/s]	TRA	Symbol Rate f_{sym} [kbaud]	f_x	f_H	f_L [kHz]	f_0 [Hz]	N_H	K_{SDSL} [V ²]	K_x [W/Hz]
Sym	< 2 048	both	$(R+ 8 \text{ kbit/s})/3$	f_{sym}	$f_x/2$	5	1	6	7,86	$0,5683 \times 10^{-4}$
Sym	$\geq 2 048$	both	$(R+ 8 \text{ kbit/s})/3$	f_{sym}	$f_x/2$	5	1	6	9,90	$0,5683 \times 10^{-4}$
Asym	2 048	LTU	$(R+ 8 \text{ kbit/s})/3$	$2 \times f_{sym}$	$f_x \times 2/5$	5	1	7	16,86	$0,5683 \times 10^{-4}$
Asym	2 048	NTU	$(R+ 8 \text{ kbit/s})/3$	f_{sym}	$f_x \times 1/2$	5	1	7	15,66	$0,5683 \times 10^{-4}$
Asym	2 304	LTU	$(R+ 8 \text{ kbit/s})/3$	$2 \times f_{sym}$	$f_x \times 3/8$	5	1	7	12,48	$0,5683 \times 10^{-4}$
Asym	2 304	NTU	$(R+ 8 \text{ kbit/s})/3$	f_{sym}	$f_x \times 1/2$	5	1	7	11,74	$0,5683 \times 10^{-4}$

Power back-off (both directions)

The SDSL transmitter signal model includes a mechanism to cutback the power for short loops, and will be activated when the "Estimated Power Loss" (EPL) of the loop is below a threshold loss PL_{thres} . This EPL is defined as the ratio between the total transmitted power (in W), and the total received power (in W). This loss is usually expressed in dB as EPL_{dB} .

This power back-off (PBO) is equal for all in-band transmit frequencies, and is specified in expression 5. It should be noted that this model is based on a smooth cutback mechanism, although practical SDSL modems may cut back their power in discrete steps ("staircase"). This expression is simplified for simulation purposes. The SDSL power back-off is described in TS 101 524 [5], clause 9.2.6.

$$PBO_{dB} = \begin{cases} 0dB & (if \Delta_{PL} < 0) \\ \Delta_{PL} & (if 0 \leq \Delta_{PL} \leq 6dB) \\ 6dB & (if \Delta_{PL} > 6dB) \end{cases} \quad \text{where } \Delta_{PL} = (PL_{thres,dB} - EPL_{dB})$$

Expression 5: Power back-off of the transmitted signal (in both directions), as a function of the Estimated Power Loss (EPL) and a threshold loss of $PL_{thres,dB} = 6,5 \text{ dB}$, and represents some average of the "staircase"

4.11 Transmitter signal model for "EC ADSL over POTS"

The PSD template for modelling the "EC ADSL over POTS" (TS 101 388 [7]) transmit spectrum (EC variant) is defined in terms of break frequencies, as summarized in table 9. The associated values are constructed with straight lines between these break frequencies, when plotted against a *logarithmic* frequency scale and a *linear* dBm scale. The frequency Δf in this table refers to the spacing of the DMT sub carriers of ADSL. The source impedance equals $R_s = 100 \Omega$.

NOTE: These models do not apply to the associated ADSL2 (annex A) variant (ITU-T Recommendation G.992.3 [9]).

Table 9: PSD template values at break frequencies for modelling "EC ADSL over POTS"

EC ADSL over POTS DMT carriers	Up [7:31]	EC ADSL over POTS DMT carriers	Down [7:255]
f [Hz]	P [dBm/Hz]	f [Hz]	P [dBm/Hz]
0	-101	0	-101
3,99k	-101	3,99 k	-101
4 k	-96	4 k	-96
$6,5 \times \Delta f$ ($\approx 28,03$ k)	-38	$6,5 \times \Delta f$ ($\approx 28,03$ k)	-40
$31,5 \times \Delta f$ ($\approx 135,84$ k)	-38	$256 \times \Delta f$ ($= 1\,104$ k)	-40
$53,0 \times \Delta f$ ($\approx 228,56$ k)	-90	1,250 M	-45
686 k	-100	1,500 M	-70
1,411 M	-100	2,100 M	-90
1,630 M	-110	3,093 M	-90
5,275 M	-112	4,545 M	-112
30 M	-112	30 M	-112
$\Delta f = 4,3125$ kHz		$\Delta f = 4,3125$ kHz	

Power cut back (downstream only)

The transmitter signal model includes a mechanism to cut-back the power for short loops, and will be activated when the band-limited power P_{rec} , received within a specified frequency band at the other side of the loop, exceeds a threshold value P_{thres} . This frequency band is from $6,5 \times \Delta f$ to $18,5 \times \Delta f$, where $\Delta f = 4,3125$ kHz, and covers 12 consecutive sub carriers (7 through 18).

The cut back mechanism reduces the PSD template to a level PSD_{max} , as specified in expression 6, for those frequencies where the downstream PSD template exceeds this level. For all other frequencies, the PSD template remains unchanged. Note that this model is based on a smooth cutback mechanism, although practical ADSL modems may cut back their power in discrete steps ("staircase").

$$PSD_{max,dBm} = \begin{cases} -40dBm/Hz & (if \Delta_p < 0dB) \\ -40dBm/Hz - 2 \times \Delta_p & (if 0 \leq \Delta_p \leq 6dB) \\ -52dBm/Hz & (if \Delta_p > 6dB) \end{cases} \quad \text{where } \Delta_p = (P_{rec,dBm} - P_{thres,dBm})$$

Expression 6: Maximum PSD values of the transmitted downstream signal, as a function of the band-limited received power P_{rec} and a threshold level of $P_{thres,dBm} = 2,5$ dBm, and represents some average of the "staircase"

4.12 Transmitter signal model for "FDD ADSL over POTS"

The PSD template for modelling "FDD ADSL over POTS" (TS 101 388 [7] and ITU-T Recommendation G.992.1 [8]) transmit spectra is defined in terms of break frequencies, as summarized in tables 11 and 10.

- Table 10 is to be used for modelling "adjacent FDD modems", usually enhanced by echo cancellation for improving the separation between upstream and downstream signals. Because a guard band is not needed here, only 1 sub-carrier is left unused.

- Table 11 is to be used for modelling "guard band FDD modems", usually equipped with steep filtering for improving the separation between upstream and downstream signals. 7 sub-carriers are left unused to enable this guard band to be implemented.

The associated values are constructed with straight lines between these break frequencies, when plotted against a *logarithmic* frequency scale and a *linear* dBm scale. The frequency Δf in this table refers to the spacing of the DMT sub-carriers of ADSL. The source impedance equals $R_s = 100 \Omega$.

NOTE: These models do not apply to the associated ADSL2 (annex A) variant (ITU-T Recommendation G.992.3 [9]).

Table 10: PSD template values at break frequencies for modelling "FDD ADSL over POTS", implemented as "adjacent FDD" (with echo cancelling)

Adjacent FDD (using echo cancellation)					
FDD ADSL over POTS DMT carriers		Up [7:31]	FDD ADSL over POTS DMT carriers		Down [33:255]
f [Hz]		P [dBm/Hz]	f [Hz]		P [dBm/Hz]
0		-101	0		-101
3,99k		-101	3,99 k		-101
4 k		-96	4 k		-96

1,630 M		-110	1,500 M		-70
5,275 M		-112	2,100 M		-90
30 M		-112	3,093 M		-90
			4,545 M		-112
			30 M		-112
$\Delta f = 4,3125$ kHz			$\Delta f = 4,3125$ kHz		

NOTE: This PSD allocates 7 unused sub-carriers.

Power cut back (downstream only)

The transmitter signal model includes a mechanism to cut back the power for short loops, using the same mechanism as specified in expression 6, for modelling "EC ADSL over POTS" transmitters.

4.13 Transmitter signal model for "EC ADSL over ISDN"

The PSD template for modelling the "EC ADSL over ISDN" (TS 101 388 [7] and ITU-T Recommendation G.992.1 [8]) transmit spectrum (EC variant) is defined in terms of break frequencies, as summarized in table 12. The associated values are constructed with straight lines between these break frequencies, when plotted against a *logarithmic* frequency scale and a *linear* dBm scale. The frequency Δf in this table refers to the spacing of the DMT sub-carriers of ADSL. The source impedance equals $R_s = 100 \Omega$.

NOTE: These models do not apply to the associated ADSL2 (annex B) variant (ITU-T Recommendation G.992.3 [9]).

Table 12: PSD template values at break frequencies for modelling "EC ADSL over ISDN"

EC ADSL over ISDN DMT carriers		Up [33:63]		EC ADSL over ISDN DMT carriers		Down [33:255]	
f [Hz]		P [dBm/Hz]		f [Hz]		P [dBm/Hz]	
0		-90		0		-90	
50		-90		50 k		-90	
22,5×Δf (≈ 97,03 k)		-85,3		22,5×Δf (≈ 97,03 k)		-85,3	
32,5×Δf (≈ 140,16 k)		-38		32,5×Δf (≈ 140,16 k)		-40	
63,5×Δf (≈ 273,84 k)		-38		256×Δf (= 1 104 k)		-40	
67,5×Δf (≈ 291,09 k)		-55		1,250 M		-45

5,275 M		-112					
30 M		-112					
Δf = 4,3125 kHz				Δf = 4,3125 kHz			

Power cut back (downstream only)

The transmitter signal model includes a mechanism to cut-back the power for short loops, and will be activated when the band-limited power P_{rec} , received within a specified frequency band at the other side of the loop, exceeds a threshold value P_{thres} . This frequency band is from $35.5 \times \Delta f$ to $47.5 \times \Delta f$, where $\Delta f = 4.3125$ kHz, and covers 12 consecutive sub carriers (36 through 47).

The cut back mechanism reduces the PSD template to a level PSD_{max} , as specified in expression 7, for those frequencies where the downstream PSD template exceeds this level. For all other frequencies, the PSD template remains unchanged. Note that this model is based on a smooth cutback mechanism, although practical ADSL modems may cut back their power in discrete steps ("staircase").

$$PSD_{max,dBm} = \begin{cases} -40dBm/Hz & (if \Delta_p < 0dB) \\ -40dBm/Hz - \frac{4}{3} \times \Delta_p & (if 0 \leq \Delta_p \leq 9dB) \\ -52dBm/Hz & (if \Delta_p > 9dB) \end{cases} \quad \text{where } \Delta_p = (P_{rec,dBm} - P_{thres,dBm})$$

Expression 7: Maximum PSD values of the transmitted downstream signal, as a function of the band-limited received power P_{rec} and a threshold level of $P_{thres,dBm} = -0,75$ dBm, and represents some average of the "staircase"

4.14 Transmitter signal model for "FDD ADSL over ISDN"

The PSD template for modelling "FDD ADSL over ISDN" (TS 101 388 [7] and ITU-T Recommendation G.992.1 [8]) transmit spectra is defined in terms of break frequencies, as summarized in tables 14 and 13.

- Table 13 is to be used for modelling "adjacent FDD modems", usually enhanced by echo cancellation for improving the separation between upstream and downstream signals. Because a guard band is not needed here, no sub-carrier is left unused.

- Table 14 is to be used for modelling "guard band FDD modems", usually enhanced by steep filtering for improving the separation between upstream and downstream signals. 7 sub-carriers are left unused to enable this guard band to be implemented.

The associated values are constructed with straight lines between these break frequencies, when plotted against a *logarithmic* frequency scale and a *linear* dBm scale. The frequency Δf in this table refers to the spacing of the DMT sub-carriers of ADSL. The source impedance equals $R_s = 100 \Omega$.

NOTE: These models do not apply to the associated ADSL2 (annex B) variant (ITU-T Recommendation G.992.3 [9]).

Table 13: PSD template values at break frequencies for modelling "FDD ADSL over ISDN", implemented as "adjacent FDD" (with echo cancelling)

Adjacent FDD (using echo cancellation)					
FDD ADSL over ISDN DMT carriers		Up [33:63]	FDD ADSL over ISDN DMT carriers		Down [64:255]

NOTE: This PSD allocates 7 unused sub-carriers.					

Power cut back (downstream only)

The transmitter signal model includes a mechanism to cut back the power for short loops, using the same mechanism as specified in expression 7, for modelling "EC ADSL over ISDN" transmitters.

4.15 Transmitter signal model for "ADSL2/J" (All Digital Mode, FDD, annex J)

The PSD template for modelling the "ADSL2/J" transmit spectrum is defined in terms of break frequencies, as summarized in table 15. The associated values are constructed with straight lines between these break frequencies, when plotted against a *logarithmic* frequency scale and a *linear* dBm scale. The frequency Δf in this table refers to the sub-carrier spacing of the DMT tones of ADSL. The source impedance equals 100 Ω .

Table 15: PSD template values at break frequencies for modelling "ADSL2/J" - The values for f_1 ... f_4 and PSD_1 ... PSD_3 are specified in table 16

ADSL2/J DMT carriers		Up [1:k]		ADSL2/J DMT carriers		Down [64:255]

Power back-off

NOTE: The specification of power back-off is left for further study.

4.17 Transmitter signal model for "VDSL1"

VDSL is defined for a range of scenarios, each with its own template PSD. The ETSI VDSL standard (TS 101 388 [7]) has foreseen the various pairs of PSD templates for upstream and downstream transceivers, as summarized in tables 19 to 22.

The PSD template for modelling each of these "VDSL" transmit spectra, is defined in terms of break frequencies, as specified in tables 23 to 26 and in tables 27 to 30. The associated values are constructed with straight lines between these break frequencies, when plotted against a *logarithmic* frequency scale and a *linear* dBm scale. The source impedance is equal to the selected design impedance, and can be $R_V = 135 \Omega$ or $R_V = 100 \Omega$.

NOTE: The templates below do not take into account that additional PSD reduction mechanisms like pre-defined downstream PSD limitation or automatic upstream power back-off can be applied in a practical situation. For the downstream signals of FTTEEx-VDSL, and for the downstream signals of FTTCab-VDSL M2 (variant A and B), the transmitter is not allowed to fill the complete PSD mask, because it violates the maximum transmit power allowed. The transmitter has then to reduce the PSD, until the power constraint is fulfilled. This reduction mechanism is not specified in the VDSL standard. The templates below are based on a specific modem power reduction method using the ceiling power cutback. The actual transmit PSD could therefore differ from one modem to the other.

4.18 Transmitter signal models for “VDSL2”

The PSD templates for VDSL2 are to model the VDSL variants being defined in ITU specification G993.2 [13].

The complexity of VDSL2 (many flavors many kinds of PSD shaping/PBO in downstream and upstream, power restrictions) requires a break-down of the specification of a PSD template for a particular scenario. Figure 1 illustrates how the VDSL2 transmitter model can be broken down into four individual building blocks. Each block has its own set of controlling parameters, to control one or more aspects of the output spectrum of VDSL2. A baseline “noise floor” being defined for all frequencies of interest, as input for the first building block.

- A “PSD band constructor” that enables the bands requested by the user above this noise floor.
- A “PSD shaper” that modifies the shape of an intermediate template PSD by a parametric formula, guided by the spectrum to be protected in the downstream and by the desired received signal in the upstream.
- A “PSD Notcher” that can “punch” notches in a shaped PSD, to prevent egress levels being too high in radio bands of interest.
- A “PSD power restrictor” that can modify a PSD (template) in such a way that the aggregate power of the PSD does not exceed some pre-defined upper limit.

In addition, pre-defined tables are provided for the “PSD band constructor” to generate spectra that are compliant with those being defined in the ITU specification G993.2 [13].

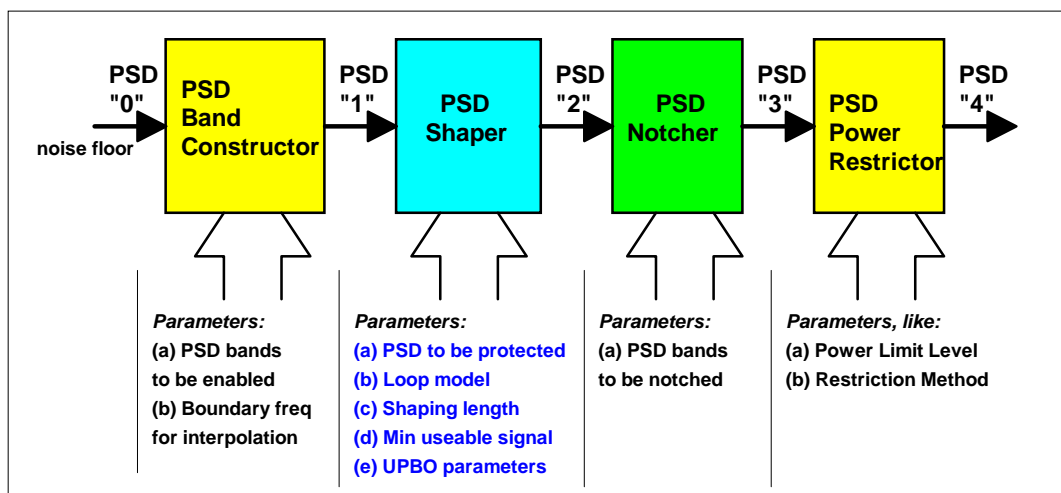

Figure 1: Building blocks of a VDSL2 transmitter model, for defining a wide range of PSD templates with only a few PSD tables and formulas.

4.18.1 Noise floor

The noise floor defines a base line PSD, as input for the first building block. Suitable noise floors are pre-defined in table 31, but the model is not restricted to any of these pre-defined PSDs.

Table 31: Pre-defined noise floors, derived from clause B4.1 in G993.2 [13], as starting PSD for building block #1.

7.05M	interp	interp	-112
30M	-112	-112	-112

4.18.2 Building block #1 for “PSD Band Constructor”

Building block #1 for the “PSD band constructor” generates a static PSD template, selected from a set of PSD bands. Pre-defined spectra are provided by means of break point tables, up to 30 MHz, but the use of the algorithmic model is not restricted to these tables.

The model in figure 2 starts from a PSD, representing a *noise floor*, and combines it subsequently with as many PSD bands as required. A pre-defined noise floor is provided as well.

Combining means within this context: taking the *maximum* of two PSD levels, where one PSD is the selected PSD band, and the other is a PSD being built-up in previous steps (starting with the noise floor). This maximum is to be evaluated for all frequencies within the selected PSD band. Outside that band, the PSD will remain unchanged.

Figure 3 visualizes such a step in reconstructing a resulting PSD from these two “input” PSDs.

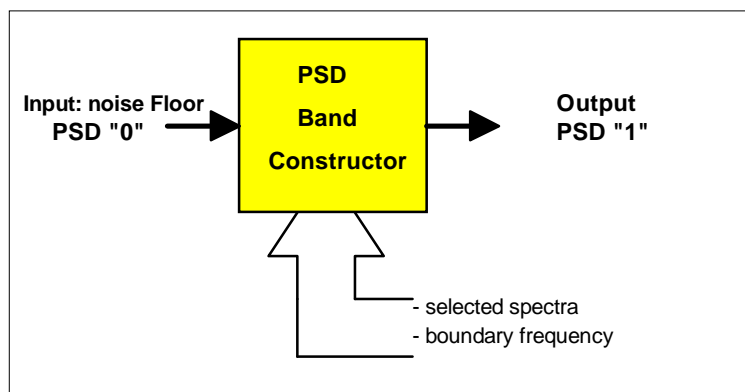

Figure 2: Conceptual description of the “PSD Band Constructor” block.

Figure 3: Illustration on how building block #1 combines two PSDs into a third.

The PSD bands can have arbitrary spectra and can be defined in many ways. A commonly used approach is a PSD definition by means of break-point tables. Such a PSD is derived via interpolation, by interconnecting the breakpoints via a straight line when plotted on a linear dB scale. This is called “linear” interpolation, when plotted on a linear frequency axis, “logarithmic” interpolation, when plotted on a logarithmic axis, and “mixed” interpolation when both methods are applied in different frequency bands. When mixed interpolation applies, the boundary frequencies are to be specified as well.

For the purpose of VDSL2 modelling pre-defined PSD bands are provided by means of breakpoint tables, as specified in table 35 to 45, and by a naming convention summarized in table 34. The values have been derived from G993.2 [13]. Each PSD band is essentially the combination of an in-band PSD and transition PSD(s).

For all cases only one boundary frequency applies (f_{ipb}), based on the following convention:

- if $f \leq f_{ipb}$ do logarithmic interpolation
- if $f > f_{ipb}$ do linear interpolation

Table 32 summarizes a set of pre-defined combinations of boundary frequencies, derived from G993.2 ([13], amendment 1).

Table 32: Pre-defined combinations of boundary frequencies, separating logarithmic from linear interpolation of break point tables.

bandplan	f_{ipb} upstream	f_{ipb} downstream	Recommended when the following downstream band is included:
998	3575 kHz	138 kHz	DS1L.A_998
	3575 kHz	276 kHz	DS1L.B_998
998ADE	3575 kHz	138 kHz	DS1L.A_998
	3575 kHz	276 kHz	DS1L.B_998
997	2825 kHz	138 kHz	DS1L.A_997
	2825 kHz	276 kHz	DS1L.B_997
HPE	<TBD>	<TBD>	<TBD>
	<TBD>	<TBD>	<TBD>

4.18.3 Building block #2 for “PSD Shaper”

Building block #2 is typically algorithmic in nature, roughly following the way it is formulated in G997.1 [16]. A difference is that shaping is to be applied in this building block to PSD templates and not to PSD masks. The model in figure 4 provides the generic idea, but details are currently left for further study.

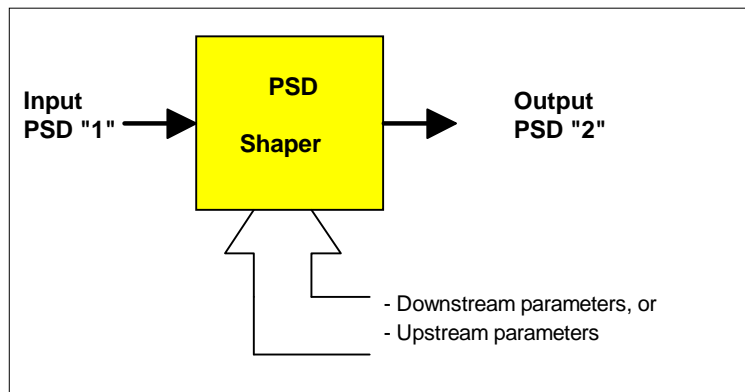

Figure 4: Conceptual description of the “PSD Shaper” block.

4.18.4 Building block #3 for “PSD notcher”

Building block #3 enables to punch notches in the spectrum, to reduce the effect of unwanted radiated emissions from VDSL2 causing undue interference to existing licensed users of that part of the spectrum. The description of this building block is roughly the same as for building block #2 (“PSD band constructor”), but its influence on the overall PSD will be different when shaping (in block #3) has been applied. The model in figure 5 starts from an input PSD and combines it subsequently with as many notching PSDs as required.

Combining means within this context: taking the *minimum* of two PSD levels, where one PSD is the selected notching PSD, and the other is a PSD being built-up in previous steps. This minimum is to be evaluated for all frequencies within the band of the selected notching PSD. Outside that band, the PSD will remain unchanged.

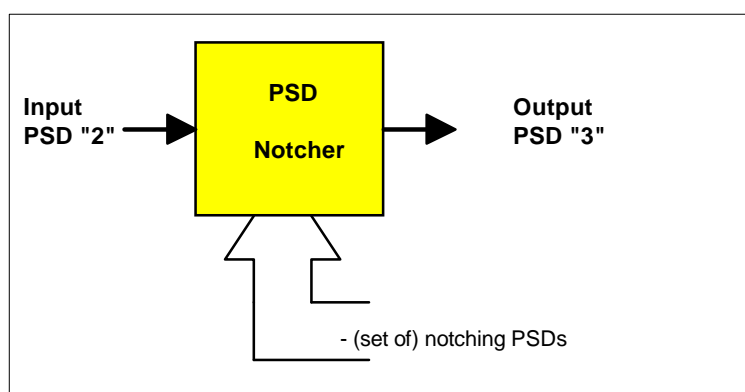

Figure 5: Conceptual description of the “PSD Notcher” block.

Table 33 summarizes a set of pre-defined notching PSDs, suitable for reducing egress into internationally standardized amateur radio bands. The model is not restricted to these pre-defined notching PSDs. The numbers are derived from the

ETSI VDSL standards [11,12]. If required, this notching can be repeated for multiple frequency intervals when more bands are to be notched. In that case the controlling parameter of this model is a set of notching PSDs.

Table 33: Break point tables of several pre-defined notching PSDs.

4.18.5 Building block #4 for “PSD Power Restrictor”

Building block #4, shown in figure 6, enables to cut-back the overall PSD when its aggregate power appears to be above a certain power limit. Such a cut-back is to be applied when for instance a modem implementation is unable to generate powers beyond that limit, or when the output PSD has to be compliant with maximum values specified by the profiles from G993.2 [13].

Different modem implementations may follow different strategies to cope with power limitations, and therefore different restriction methods can be applied to this model. A few restriction methods that can ensure that the aggregate power of a modified PSD does not exceed a certain maximum value are pre-defined below, but other methods are not excluded:

- **Attenuator method.** This power restriction requires an algorithm that causes a (frequency independent) attenuation of the full PSD. When the aggregate power of the PSD exceeds a specified limit, the algorithm is to increase this attenuation until a value that makes the aggregate power of the PSD equal to the specified limit. This method is very simple, and is often inadequate to approximate the power restriction in a real modem implementation.
- **Water-filling method.** This power restriction requires an algorithm that clips all PSD values above a certain (frequency independent) “ceiling PSD value”. When the aggregate power of the PSD exceeds a specified limit, the algorithm is to lower this “ceiling” down to a value that makes the aggregate power of the PSD equal to the specified limit. This method is typically iterative in nature but rather straightforward.
- **Lower curtain method.** This power restriction requires an algorithm that replaces all PSD values up to a certain “curtain” frequency by a pre-defined PSD floor. When the aggregate power of the PSD exceeds a specified limit, the algorithm is to raise this “curtain” frequency up to a value that makes the aggregate power of the PSD equal to the specified limit. This method is also typically iterative in nature and rather straightforward as well.
- **Upper curtain method.** This power restriction method is similar to the lower curtain method, with the difference that in this method all PSD values above a certain “curtain” frequency are to be replaced by a pre-defined PSD floor.

Other methods may be applied too, but have not been described here.

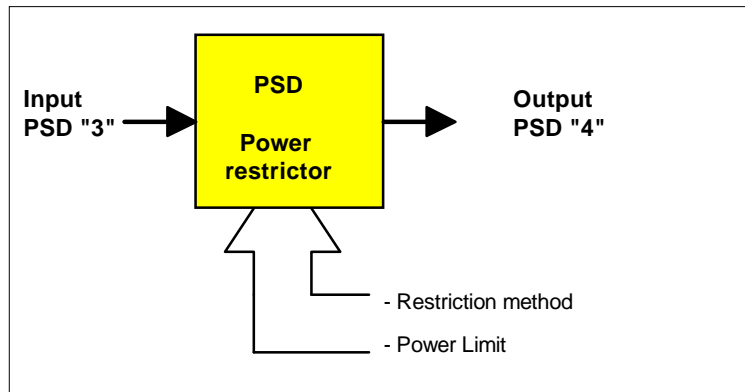

Figure 6: Input/Output Baseline PSD Power Restrictor.

4.18.6 Pre-defined downstream tables for “PSD Band Constructor”

The PSD band constructor in building block #1 can be controlled via an arbitrary number of PSD bands. Pre-defined PSD bands for downstream transmission are summarized in table 35 to 39 and specified by means of breakpoints. Each PSD band has its own (unique) identifier (summarized in table 34), for convenient referencing. A full VDSL2 transmit signal can be built-up from a proper selection of these PSD bands. Examples of meaningful combinations can be found in table 46.

The values are constructed from the breakpoints of G993.2 masks [13], roughly by correcting 3.5dB difference between mask and template for in-band frequencies, and roughly by correcting the PSD according to the constraints in 1 MHz resolution bands for out-of-band frequencies. In addition, some of the pre-defined values are adjusted via a pragmatic compromise between simplicity and ITU details.

The values associated with in-band frequencies are highlighted, for convenient interpretation of these tables.

Table 34: Summary of pre-defined PSD bands, for downstream.

4.18.7 Pre-defined upstream tables for “PSD Band Constructor”

The PSD band constructor in building block #1 can be controlled via an arbitrary number of PSD bands. Pre-defined PSD bands for upstream transmission are summarized in table 41 to 45 and specified by means of breakpoints. Each PSD bands has its own (unique) identifier (summarized in table 40), for convenient referencing. A full VDSL2 transmit signal can be built-up from a proper selection of these PSD bands. Examples of meaningful combinations can be found in table 46.

The values are constructed from the breakpoints of G993.2 masks [13], roughly by correcting 3.5dB difference between mask and template for in-band frequencies, and roughly by corrected the PSD according to the constraints in 1 MHz resolution bands for out-of-band frequencies. In addition, some of the pre-defined values are adjusted via a pragmatic compromise between simplicity and ITU details.

Table 40: Overview of pre-defined PSD bands for upstream.

4.18.8 Example definitions of VDSL2 transmitters

The above pre-defined break point tables enable the construction of all PSD combinations (profiles and band plans) being identified in G993.2 [13]. For example, table 46 shows a full elaboration for several ITU profiles within limiting mask “B8-4” (also known as “998-M2x-A”) and “B8-6” (also known as “998-M2x-B”). In these examples, shaping and notching is disabled. The profiles differ in their combination of allocated bands (within the limiting mask) and maximum power. When a VDSL2 transmitter is specified in this way, its output signal is fully defined.

Table 47 shows for each limiting masks being defined in G993.2 [13] what break-point tables can be considered when constructing the PSD for a specific profiles. A full elaboration for all possible combinations has been omitted here for sake of brevity.

Table 46: Full elaboration of the VDSL2 transmit PSD for a few profiles within limiting mask "B8-4".

ITU profile + limiting mask	PSD Band constructor		PSD Shaper	PSD Notcher	PSD Power restrictor
8b, B8-4 (8b, 998-M2x-A)	NF_998 $f_{ipb} = 138$ kHz	DS1L.A_998 DS1U.M2_998 DS2.M2_998	<none>	<none>	20.5 dBm Water-fill

5 Generic receiver performance models for xDSL

A receiver performance model is capable of estimating up to what performance a data stream can be recovered from a noisy signal. In all cases it assumes that this recovery meets predefined quality criteria such as a maximum error better than $BER < 10^{-7}$ (Bit Error Ratio).

The word *performance* refers within this context to a variety of quantities, including noise margin, signal margin and maximum data rate. When the receiver is ideal (zero internal receiver noise, infinite echo cancellation, etc), the noise margin and signal margin become equal.

Performance models are implementation and line code specific. Performance modelling becomes more convenient when broken down into a combination of smaller sub models (see figure 7).

- A line code independent *input* (sub)model that evaluates the effective SNR from received signal, received noise, and various receiver imperfections. Details are described in clause 5.1.
- A line code dependent *detection* (sub)model that evaluates the performance (e.g. the noise margin at a specified bitrate) from the effective SNR. Details are described in clause 5.2.
- An (optional) *echo-coupling* (sub)model that evaluates what portion of the transmitted signal flows into the receiver. Details are described in clause 5.3.

The flow diagram in figure 7 represents an xDSL transceiver that is connected via a common wire pair to another transceiver (not shown). This wire pair transports the transmitted signal, received signal and received noise simultaneously.

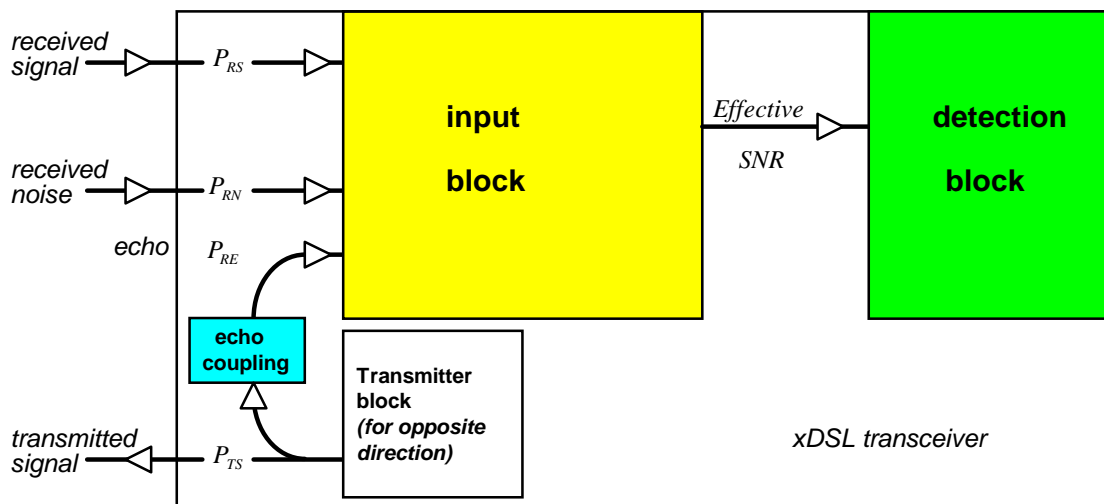

Figure 7: Flow diagram of a transceiver model, build up from individual sub models

The **input block** of the flow diagram in figure 7 requires values for *signal*, *noise* and *echo*. The flow diagram illustrates this for an xDSL transceiver that is connected via a common wire pair to another transceiver (not shown), which transports the following three flows simultaneously:

- The received *signal* power P_{RS} carries the data that is to be recovered. This signal originates from the transmitter at the other side of the wire pair, and its level is attenuated by cable loss.
- The received *noise* power P_{RN} is all that is received when the transmitters at both sides of the link under study are silent. The origin of this noise is mainly crosstalk from internal disturbers connected to the same cable (crosstalk noise), and partly from external disturbers (ingress noise).
- The received *echo* power P_{RE} is all that is received when the transmitter at the other end of the wire pair is silent, as well as all internal and external disturbers. It is a residue that will be received when a transmitter and a receiver are combined into a transceiver, and co-connected via a hybrid to the same wire pairs. No hybrid is perfect, so a portion (P_{RE}) of the transmitted signal (P_{TS}) will leak into the receiver and is identified as echo.

Usually most of this is due to mismatch between the termination impedance, presented by the transceiver and the near end of the wire pair. Gauge changes along the wire pair also contribute echo.

- When the hybrid of that transceiver is unbalanced due to mismatched termination impedances (of the cable), then a portion (P_{RE}) of the transmitted signal (P_{TS}) will leak into the receiver and is identified as echo.

The input block in figure 7 evaluate a quantity called *effective SNR* (Signal to noise Ratio) that indicates to what degree the received signal is deteriorated by noise, residual echo and all kinds of implementation imperfections. Due to signal processing in the receiver, the *input SNR* (the ratio between signal power, and the power-sum of noise and echo) will change into the *effective SNR* at some virtual internal point at the receiver. The effective SNR can be better or worse than the input SNR. Receivers with build-in echo cancellation can take advantage of a-priori knowledge on the echo, and can suppress most of this echo to improve the effective SNR. On the other hand, all analogue receiver electronics produce shot noise and thermal noise, the A/D-converter produces quantization noise, and the equalization has its limitations as well. The combination of all these individual imperfections deteriorates the effective SNR.

In principle all parameters of the effective SNR can be assumed as frequency dependent, but this dependency has been omitted here for reasons of simplicity. In addition, external change of signal and noise levels will modify the value of this effective SNR.

The **detection block** of the flow diagram in figure 7 requires this effective SNR to evaluate from that the performance as *margin* (such as noise margin, or signal margin). For many detection models, this margin is not provided by a closed expression, but by an equation from which this margin is to be solved. A simulation program may follow an iterative approach to solve this: controlling this margin in the input block so that the effective SNR changes and the equation in the detection block can be met.

In principle, the detection block is dedicated to line-code specific imperfections only, but may also include receiver imperfections that are not covered by the input block.

The **echo-coupling block** is optional, in case the input block does not deal with the related imperfections. Simple (first order) models for the input block cannot distinguish between receiver imperfection originated from echo and from other causes. When these simplified models are used, the echo-coupling block will not be required in the receiver performance model.

Clause 5 details (sub)models for the afore mentioned blocks in a receiver performance model, but is restricted to *generic* performance models only. Clause 6 is dedicated to implementation *specific* models by additionally assigning values to all parameters of a generic model.

5.1 Generic input models for effective SNR

An input (sub) model describes how to evaluate the effective SNR, as intermediate result (see figure 7), from various input quantities and imperfections. To simplify further analysis of performance quantities like *noise margin* and *signal margin*, the effective SNR is often expressed in its *offset format*, characterized by an additional parameter m . The associated expression is defined for each model individually.

By using this parameter m the external noise level can be increased (for noise margin calculations) or the external signal level can be decreased (for signal margin calculations). The convention is that when $m=1$ (equals zero dB) the effective *offset SNR* equals the effective SNR itself. When the value of parameter m increases, the effective offset SNR decreases.

5.1.1 First order input model

This input model is a simplified model that assumes that the SNR of the input signal is internally modified by internal receiver noise (P_{RNO}). Most imperfections of the receiver (such as front-end noise, imperfect echo suppression, imperfect equalization and quantization noise) are assumed to be concentrated in a single virtual internal noise source (P_{RNO}). Figure 8 shows the flow diagram of an xDSL transceiver model showing the elements of a first order input model for effective SNR evaluation, and how to incorporate it in the receiver performance model.

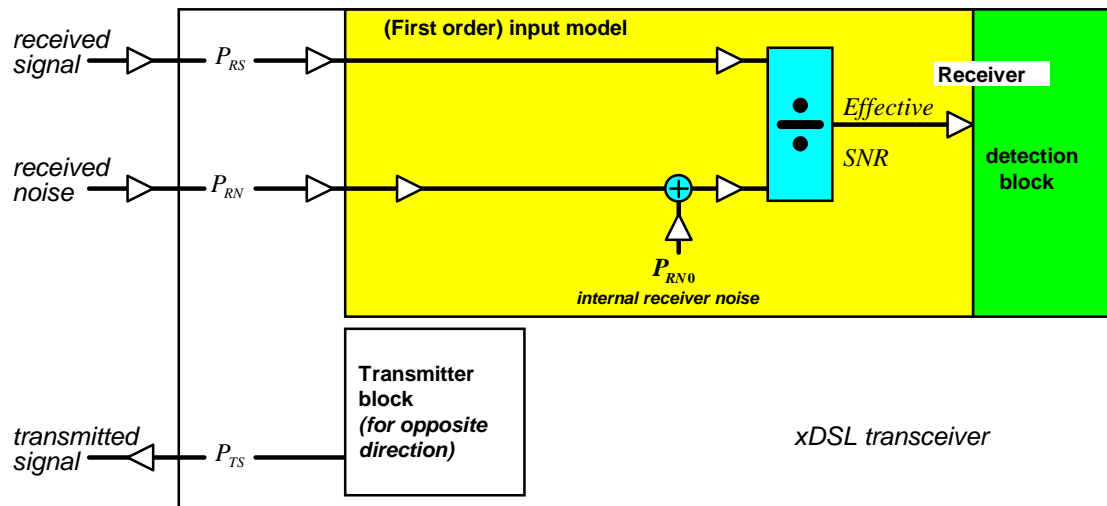

Figure 8: Flow diagram of a transceiver model that incorporates a linear first order input model for the determination of the effective SNR

Expression 8 summarizes how to evaluate the effective SNR for this model, in plain and in offset format. Table 48 summarizes the associated parameters.

Plain format:	$SNR(f) = \frac{P_{RS}(f)}{P_{RN}(f) + P_{RN0}(f)}$
Noise offset format:	$SNR_{ofs,N}(m, f) = \frac{P_{RS}(f)}{(P_{RN}(f) \times m) + P_{RN0}(f)}$
Signal offset format:	$SNR_{ofs,S}(m, f) = \frac{P_{RS}(f) / m}{P_{RN}(f) + P_{RN0}(f)}$

Expression 8: Effective SNR, in various formats, when using the first order input model

Table 48: Associated parameters and quantities for a first order input model - All PSD levels may be frequency dependent. Constant $P_0=1mW$

Input quantities	linear	in dBm or dB	remarks
Received signal power	P_{RS}	$10 \times \log_{10}(P_{RS}/P_0)$	External signal
Received noise power (crosstalk)	P_{RN}	$10 \times \log_{10}(P_{RN}/P_0)$	External noise
Model Parameters			
Internal receiver noise power	P_{RN0}	$10 \times \log_{10}(P_{RN0}/P_0)$	Internal noise
Output quantities			
Signal to noise ratio (effective)	SNR	$10 \times \log_{10}(SNR)$	Frequency dependent

5.2 Generic detection models

This clause identifies several generic (sub) models for the detection block: one line code independent model derived from the Shannon capacity limit, and various line code dependent models dedicated to PAM, CAP/QAM or DMT line coding. Table 49 summarizes the naming convention for input and output quantities.

Table 49: Symbols used for input and output quantities of detection models

Input quantities	linear	in dB or dBm	remarks
Signal to Noise Ratio	SNR	$10 \times \log_{10}(SNR)$	Ratio of powers (frequency dependent)
Output quantities			
Noise margin	m_n	$10 \times \log_{10}(m_n)$	Ratio of noise powers
Signal margin	m_s	$10 \times \log_{10}(m_s)$	Ratio of signal powers

On input, the detection block requires an effective SNR, as provided by the input block. This SNR is a function of the frequency f . When the offset format is used for describing the SNR, it will also be a function of the offset parameter m . This offset format is specified individually for each model in clause 5.1.

On output, the detection block evaluates a signal margin m_n (or a noise margin m_s when more appropriate). This margin parameter is an important measure for the transport quality that is achieved under noisy conditions.

- The *Noise Margin* m_n indicates how much the received noise power can increase before the transmission becomes unreliable.
- The *Signal Margin* m_s indicates how much the received signal power can decrease before the transmission becomes unreliable.

Unless explicitly specified otherwise, the word *margin* refers in the present document to *noise margin*.

NOTE: From an xDSL deployment point of view, the analysis of noise margin is preferred over signal margin, since the (crosstalk) noise is the quantity that may increase when more systems are connected to the same cable. Many xDSL implementations, however, do report margin numbers that are not exactly equal to this noise margin, since the detection circuitry cannot make a distinction between external noise (due to crosstalk) and internal noise (due to imperfect electronics). These margins are often an estimate closer in value to the signal margin than to the noise margin.

5.2.1 Generic Shifted Shannon detection model

The calculation of the margin m using the generic Shifted Shannon detection model, is equivalent to solving the equation in expression 9. It has been derived from Shannon's capacity theorem, by reducing the effective SNR ("shifting" on a dB scale) by the SNR-gap G , to account for the imperfections of practical detectors. The associated parameters are summarized in table 50.

The effective SNR is to be evaluated by using one of the input models described in clause 5.1. Depending on what offset format is used for the SNR expression (see clause 5.1), the calculated margin m will represent the noise margin m_n or the signal margin m_s .

$$f_b = \int_{f_c - B/2}^{f_c + B/2} \log_2 \left(1 + \frac{SNR_{ofs}(m, f)}{\Gamma} \right) \times df$$

Expression 9: Equation of the Shifted Shannon detection model, for solving the margin m

Table 50: Parameters used for Shifted Shannon detection models

Model Parameters	linear	in dB	Remarks
SNR gap	G	$10 \times \log_{10}(G)$	
Line rate	f_b		= data rate (all payload bits that are transported in 1 sec) + overhead bitrate
Centre frequency	f_c		Centre value of the most relevant spectrum
Bandwidth	B		Width of most relevant spectrum
Margin	m	$10 \times \log_{10}(m)$	

The various parameters used within this generic detection model are summarized in table 50. The model can be made specific by assigning values to all these model parameters.

- The SNR-gap (G) is a performance parameter that indicates how close the detection approaches the Shannon capacity limit.
- The line rate (f_b) is usually higher than the data rate (0 % to 30 %) to transport overhead bits for error correction, signalling and framing.
- The bandwidth is a parameter that indicates what frequency range of the received spectrum is relevant for data transport. The model assumes that only frequencies within this range can pass the receive filters.

5.2.2 Generic PAM detection model

The calculation of the margin m using the generic PAM detection model is equivalent to solving the equation in expression 10. This model assumes ideal decision feedback equalizer (DFE) margin calculations. The associated parameters are summarized in table 51.

The effective SNR is to be evaluated by using one of the input models described in clause 5.1. Depending on what offset format is used for the SNR expression (see clause 5.1), the calculated margin m will represent the noise margin m_n or the signal margin m_s .

$$SNR_{req} = \Gamma \times (2^{2 \times b} - 1) = \exp \left(\frac{1}{f_s} \times \int_0^{f_s} \ln \left(1 + \sum_{n=N_L}^{N_H} SNR_{ofs}(m, f + n f_s) \right) \times df \right)$$

Expression 10: Equation of the PAM-detection model, for solving the margin m

The SNR gap G , being used in the above expression 10, is a combination of various effects. This G parameter is often split-up into the following three parts:

- A theoretical modulation gap G_{PAM} (in the order of 9,75 dB, at BER=10⁻⁷).
- A theoretical coding gain G_{coding} (usually in the order of 3 dB to 5 dB), to indicate how much additional improvement is achieved by the chosen coding mechanism.
- An empirical implementation loss G_{impl} (usually a few dB as well), indicating how much overall performance degradation is caused by implementation dependent imperfections (e.g. echo cancellation, analogue front end realization, equalization, etc), without identifying its true cause.

When G is split-up into the above three parts, its value shall be evaluated as follows:

$$\text{SNR gap (linear):} \quad G = G_{PAM} / G_{coding} \times G_{impl}$$

$$\text{SNR gap (in dB):} \quad G_{dB} = G_{PAM_dB} - G_{coding_dB} + G_{impl_dB}$$

The margin value, which can be either noise margin or signal margin, is not included in the SNR gap as it is contained in the offset SNR expression as described in clause 5.1.

Table 51: Parameters used for PAM detection models

Model Parameters	linear	in dB	remarks
SNR gap (effective)	G	$10 \times \log_{10}(G)$	$= SNR_{req} / (2^{2 \cdot b} - 1)$
SNR gap in parts:	G_{PAM}	$10 \times \log_{10}(G_{PAM})$	Modulation gap for PAM
	G_{coding}	$10 \times \log_{10}(G_{coding})$	Coding gain
	G_{impl}	$10 \times \log_{10}(G_{impl})$	Implementation loss
Required SNR	SNR_{req}	$10 \times \log_{10}(SNR_{req})$	$= G \times (2^{2 \cdot b} - 1)$
Line rate	f_b		= data rate (all payload bits that are transported in 1 sec) + overhead bitrate
Symbol rate	f_s		$= f_b / b$
Bits per symbol	b		$= f_b / f_s$ (can be non-integer)
Summation range	N_L, N_H		On default: $N_L = -2$ and $N_H = +1$
Margin	m	$10 \times \log_{10}(m)$	

The various parameters in table 51 used within this generic detection model have the following meaning:

- The SNR-gap (G) and required SNR (SNR_{req}) are equivalent parameters and can be converted from one to the other. The advantage of using G over SNR_{req} is that G can be defined with similar meaning for all theoretical models in the frequency domain (Shifted Shannon, CAP, PAM, and DMT). The advantage of using SNR_{req} over G is that this quantity is closer related to the SNR observed at the decision point of the detection circuitry.
- The line rate (f_b) is usually higher than the data rate (0 % to 30 %) to transport overhead bits for error correction, signalling and framing. The symbol rate is the line rate divided by the number of bits packed together in a single symbol.
- The summation range for n is from N_L to N_H , and this range has to be defined to make this generic model specific. Commonly used values for PAM, using over sampling, are $N_L = -2$ and $N_H = +1$. This corresponds to T/3-spaced equalization. Wider ranges are not excluded.

5.2.3 Generic CAP/QAM detection model

The calculation of the margin m using the generic CAP/QAM detection model is equivalent to solving the equation in expression 11. This model assumes ideal Decision Feedback Equalizer (DFE) margin calculations. The associated parameters are summarized in table 52.

The effective SNR is to be evaluated by using one of the input models described in clause 5.1. Depending on what offset format is used for the SNR expression (see clause 5.1), the calculated margin m will represent the noise margin m_n or the signal margin m_s .

$$SNR_{req} \equiv \Gamma \times (2^b - 1) = \exp \left(\frac{1}{f_s} \times \int_0^{f_s} \ln \left(1 + \sum_{n=N_L}^{N_H} SNR_{ofs}(m, f + nf_s) \right) \times df \right)$$

Expression 11: Equation of the CAP/QAM-detection model, for solving the margin m

The (effective) SNR gap G , being used in the above expression 11, is a combination of various effects. This has been explained in more detail for the PAM detection model. The theoretical modulation gap, identified as G_{CAP} for the CAP/QAM detection model, is in the order of 9,8 dB for BER= 10^{-7} .

The margin value, which can be either noise margin or signal margin, is not included in the SNR gap as it is contained in the offset SNR expression as described in clause 5.1.

Table 52: Parameters used for CAP/QAM detection models

Model Parameters	linear	in dB	remarks
SNR gap (effective)	G	$10 \times \log_{10}(G)$	$= SNR_{req} / (2^b - 1)$
SNR gap in parts:	G_{CAP}	$10 \times \log_{10}(G_{PAM})$	Modulation gap for CAP/QAM
	G_{coding}	$10 \times \log_{10}(G_{coding})$	Coding gain
	G_{impl}	$10 \times \log_{10}(G_{impl})$	Implementation loss
Required SNR	SNR_{req}	$10 \times \log_{10}(SNR_{req})$	$= G \times (2^b - 1)$
Line rate	f_b		= data rate (all payload bits that are transported in 1 sec) + overhead bitrate
Symbol rate	f_s		$= f_b / b$
Bits per symbol	b		$= f_b / f_s$ (can be non-integer)
Summation range	N_L, N_H		On default: $N_L=0$ and $N_H=+3$
Margin	m	$10 \times \log_{10}(m)$	

The various parameters in table 52 used within this generic detection model have the following meaning:

- The SNR-gap (G) and required SNR (SNR_{req}) are equivalent parameters and can be converted from one to the other. The advantage of using G over SNR_{req} is that G can be defined with similar meaning for all theoretical models in the frequency domain (Shannon, CAP, PAM, and DMT). The advantage of using SNR_{req} over G is that this quantity is closer related to the SNR observed at the decision point of the detection circuitry.
- The line rate is usually higher than the data rate (0 % to 30 %), to transport overhead bits for error correction, signalling and framing. The symbol rate is the line rate divided by the number of bits packed together in a single symbol.
- The summation range for n is from N_L to N_H . Commonly used values for CAP/QAM systems using over sampling are $N_L=0$ and $N_H=+3$. This holds when the carrier frequency positions the spectrum low in the frequency band (e.g. CAP-based HDSL). Other values may be more appropriated when the carrier frequency moves the spectrum to higher frequencies (e.g. CAP based VDSL).

5.2.4 Generic DMT detection model

The calculation of the margin m using the generic DMT detection model is equivalent to solving the equations in expression 12, for a given line rate f_b (or given *data* line rate f_{bd}). The associated parameters are summarized in table 53, and function *load* is specified by the chosen bit-loading algorithm. The effective SNR is to be evaluated by using one of the input models described in clause 5.1. Depending on what offset format $SNR_{ofs}(m, f)$ is used to express this effective SNR for margins other than $m=1$ (equals zero dB), the solved margin m will result in the noise margin m_n or the signal margin m_s .

$$\begin{array}{l}
 b_k = \log_2 \left(1 + \frac{SNR_{ofs}(m, f_k)}{\Gamma} \right) \quad [bit / tone / symbol] \\
 f_{bd} = f_{sd} \times b = f_{sd} \times \sum_{k \in tones} load(b_k) \quad [bit / s] \\
 f_b = f_{bd} + f_{bs} \quad [bit / s]
 \end{array}$$

NOTE: The words "tone" refers to "sub-carrier" but is preferred here to express dimensions like [bits/tone].

Expression 12: Equations of the DMT-detection model, for solving the margin m for a given *data* line rate f_{bd} , and a given *data* symbol rate f_{sd} - The rate f_{sd} excludes all DMT symbols dedicated to synchronization

Bit-loading algorithm

The DMT sub-carriers are all positioned (centred) at a multiple of the sub-carrier frequency spacing Δf , and each sub-carrier theoretically may carry any fragment of a symbol, while a symbol can carry many bits (typically a few hundred or more). The way this bit space (bits per tone per symbol) is used to load each sub-carrier with bits is implementation dependent.

Bit-loading algorithms commonly use masking. Masking means skipping carriers for loading when their bit space b_k is below some predefined minimum value b_{\min} , and limiting the bit-loading to some pre-defined maximum when the bit space b_k exceeds some predefined maximum b_{\max} . This masking process is summarized in expression 13.

$b_k < b_{\min}$	\Rightarrow	$load(b_k) \equiv 0$
$b_{\min} \leq b_k \leq b_{\max}$	\Rightarrow	$load(b_k) \equiv b_k$
$b_k > b_{\max}$	\Rightarrow	$load(b_k) \equiv b_{\max}$

Expression 13: The bit loading used in (fractional) bit-loading algorithms

When the data transport is operating on its limits (margin $m=1$, or zero dB), the following bit-loading algorithms may apply, in addition to masking:

- *Fractional bit-loading* (FBL): sometimes referred to as *water-filling* - is a pure theoretical approach enabling loading of any real number of bits per symbol in any sub-carrier k (including non-integer fractions). This maximizes the use of the available capacity, but is impractical to implement.
- *Truncated bit-loading* (TBL): is a more feasible algorithm in practice, and loads on each sub-carrier k a number of bits equal to the largest non-negative integer *below* the bit space b_k .
- *Rounded bit-loading* (RBL): is also feasible in practice, and loads each sub-carrier k with a number of bits equal to the nearest non-negative integer of bit space b_k .
- *Gain adjusted bit-loading* (GABL): is a sophisticated combination of rounded bit-loading and adjustment of powers to each of the sub-carriers, so that each individual bit space b_k approaches a rounded value (minimizes the loss of capacity), while the total transmit power is kept unchanged on average.

In various applications, it may be assumed that the capacity of well-designed *gain adjusted* bit-loading algorithms closely match those achieved by *fractional* bit-loading algorithm. For the sake of simplicity, and for making capacity calculations in the present document less implementation dependent, the fractional bit-loading algorithm with constraint number of bits per sub-carrier and symbol, as in expression 13, is used as default for DMT calculations in the present document, unless specified explicitly otherwise.

SNR-Gap

The (effective) SNR gap G , being used in expression 12, is a combination of various effects. This has been explained in more detail for the PAM detection model. The theoretical modulation gap, identified as G_{DMT} for the DMT detection model, is in the order of 9,75 dB for BER= 10^{-7} .

The margin value, which can be either noise margin or signal margin, is not included in the SNR gap as it is contained in the offset SNR expression as described in clause 5.1.

Associated parameters

Table 53: Parameters used for DMT detection models

Input quantities	linear	in dB	remarks
Signal to Noise Ratio (effective value)	SNR	$10 \times \log_{10}(SNR)$	Frequency dependent ratio of powers
Model Parameters	linear	in dB	remarks
SNR gap (effective)	G	$10 \times \log_{10}(G)$	$= SNR_{req} / (2^{2 \cdot b} - 1)$
SNR gap in parts:	G_{DMT}	$10 \times \log_{10}(G_{DMT})$	Modulation gap for DMT
	G_{coding}	$10 \times \log_{10}(G_{coding})$	Coding gain
	G_{impl}	$10 \times \log_{10}(G_{impl})$	Implementation loss
Symbol rate		f_s	Symbol rate, being the total number of <i>all</i> DMT symbols, transmitted in 1 s (Thus <i>data</i> symbols and <i>synch</i> symbols)
		f_{sd}	Symbol rate fragment, being the rate of <i>data</i> symbols only (without the overhead of <i>synch</i> symbols) that carry payloads bits
Line rate		f_b	Line rate, being the total number of <i>all</i> bits (for <i>data</i> , <i>synch</i> and other overhead) that is to be transported in 1 s
		f_{bd}	Line rate fragment, caused by the bits in <i>data</i> symbols only
		f_{bs}	Line rate fragment, caused by the bits in <i>synch</i> symbols only
Available set of sub-carriers		$\{k\}$	Can be a subset of all possible sub-carriers. (e.g. $k \in [7:255]$)
Centre frequency location of tone k ; $k \in \text{tones}$		f_k	$f_k = k \times \Delta f$ $\Delta f = 4,3125 \text{ kHz}$ in all current DMT systems
Bits per data symbol		$b = \sum b_k$	$b = f_{bd} / f_{sd}$ The bits of each data symbol are spread out over all used sub-carriers, in fragments of b_k
Bit-loading algorithm		FBL TBL RBL GABL	Can be one of: <ul style="list-style-type: none"> Fractional bit-loading (a.k.a. water filling) Truncated bit-loading Rounded bit-loading Gain adjusted bit-loading
Minimum bit loading		b_{min}	Minimum number of bits per sub-carrier and per data symbol
Maximum bit loading		b_{max}	Maximum number of bits per sub-carrier and per data symbol
Output quantities	linear	in dB	remarks
Noise margin	m_n	$10 \times \log_{10}(m_n)$	
Signal margin	m_s	$10 \times \log_{10}(m_s)$	

The various parameters in table 53, used within this generic detection model, have the following meaning:

- The SNR-gap (G) is a parameter that shows how far from the Shannon capacity limit a modem is performing at a certain bit error rate.
- The symbol rate f_s , in [baud] or [symbols/s], refers to *all* symbols being transmitted in one second. Most of these are so called *data* symbols, because they carry bits for data transport, but after sending many data symbols, an additional *synch* symbol may be transmitted to keep the DMT transmission synchronized. The bits in each symbol are spread out over all involved DMT sub-carriers. The symbol rate is the sum of two fragments:
 - The *data* symbol rate f_{sd} , referring only to the rate of *data* symbols.
 - The *synch* symbol rate f_{ss} , referring only to the rate of remaining *synch* symbols.

In ADSL, for example, one additional *synch* symbol is transmitted after sending 68 *data* symbols, and 4 000 *data* symbols are transmitted in one second.

In VDSL, for example, the *data* symbol rate and (total) symbol rate are equal as there is no extra synchronization symbol as in ADSL.

- The line rate f_b [bits/s] refers to *all* bits being transmitted over the line in one second, including *all* overhead bits. Examples of overhead bits are bits for synchronization, all types of coding, the embedded operation channel, etc.

Similar to the symbol rate, the line rate is the sum of two fragments:

- The *data* line rate f_{bd} , refers to all bits in *data* symbols only, and covers payload bits as well as all overhead bits in a *data* symbol.
- The *synch* line rate f_{bs} , refers to all bits in the remaining *synch* symbols, and can be considered as 100 % overhead for transporting payload bits.

The bits in each symbol are spread out over the involved sub-carriers.

- The data rate f_d , in [bits/s], refers to the rate of *payload* bits only (also known as net data bits) that are to be transported by the DMT system. This rate does not include any transmission overhead, and is therefore lower than the line rate. Performance requirements are usually specified for these rates only, as for example the ETSI standard for ADSL (TS 101 388 [7]).
- The available sub-carriers are specified by a list of integers, indicating what centre frequencies are allocated to individual sub-carriers. For instance in ADSL it can contain any of the sub-carriers from tone 7 to tone 255.
- The centre frequency of a sub-carrier k is $k \times \Delta f$, where Δf is the sub-carrier spacing.
- b_{\min} and b_{\max} are the minimum and maximum number of bits, respectively, used in the masking process of the bit loading.

5.3 Generic models for echo coupling

5.3.1 Linear echo coupling model

This model describes a property of linear hybrids in transceivers, and models what portion of the transmitted signal couples directly into the receiver. The hybrid is characterized by two parameters:

- R_V , representing the output impedance of the transceiver. Commonly used values are the design impedances of the modems under test, including 100 Ω for ADSL and 135 Ω for SDSL.
- Z_B , representing the termination impedance that causes the hybrid to be perfectly balanced. This means that when the hybrid is terminated with this "balance impedance", no echo will flow into the receiver. For well-designed hybrids, this balance impedance is a "best guess" approximation of the "average" impedance of cables being used.

Figure 9 shows an equivalent circuit diagram of the above hybrid, represented as a Wheatstone bridge. The associated transfer function $H_E(j\omega)$ expresses what portion of the transmit signal will appear as echo.

NOTE: The identifiers P_{RE} and P_{TS} refer to power flow values used in figure 7.

Figure 9: Flow diagram of the basic model for echo coupling

When using this basic model for echo coupling in a full simulation, value R_V can be made equal to the design impedance of the modem under test, and value Z_B can be made equal to the complex and frequency dependent input impedance of the cable, terminated at the other cable end with a load impedance equal to R_V . Values for R_V and Z_B are implementation specific.

6 Specific receiver performance models for xDSL

This clause defines parameter values for the generic performance models of clause 5, to provide implementation specific models for various xDSL modems.

6.1 Receiver performance model for "HDSL.2B1Q"

The reach predicted by this calculation model, under the stress conditions (loss, noise) of the associated ETSI HDSL specification (TS 101 135 [4]), is close to the reach required by ETSI specification (TS 101 135 [4]).

The receiver performance model for ETSI compliant HDSL.2B1Q is built-up from the following building blocks:

- A first order (linear) input model for the input block, specified in clause 5.1.1, that combines all imperfections (front-end noise, residual echo, equalization errors), in one virtual noise source.
- The generic PAM detection model, specified in clause 5.2.2.
- The parameter values specified in table 55.

The parameter values, used in the receiver performance model for ETSI compliant two-pair HDSL.2B1Q/2, are summarized in table 54. Parts of them are directly based on HDSL specifications. The remaining values are based on theory and assumptions.

Table 54: Values for the parameters used in the performance model, obtained from ETSI requirements for HDSL.2B1Q/2 [4]

Model Parameter		HDSL.2B1Q/2
SNR-Gap (effective)	G_{dB}	12,25 dB
SNR-Gap in parts	G_{PAM_dB}	9,75 dB
	G_{coding_dB}	0 dB
	G_{impl_dB}	2,5 dB
Receiver noise	P_{RNO_dB}	-140 dBm/Hz
Data rate	f_d	$2 \times 1\,024$ kb/s
Line rate	f_b	1 168 kb/s
bits per symbol	b	2
Summation bounds in the PAM model	N_H	+1
	N_L	-2
Derived Parameter		
Required SNR	SNR_{req}	$G \times (2^{2b} - 1)$
	SNR_{req_dB}	$\approx 24,0$ dB
Symbol rate	f_s	$f_b / b = 584$ kbaud
NOTE:	The receiver noise in this model has an unrealistic low level, but this is irrelevant for SpM studies in a mixed noise environment. As a result, this model will give too optimistic estimates of reachable distance in scenarios without any self crosstalk or any equivalent noise with similar bandwidth.	

6.2 Receiver performance model for "HDSL.CAP"

This calculation model is capable for predicting a performance that is benchmarked against the performance requirements of an ETSI compliant HDSL-CAP modem (TS 101 135 [4]). The reach predicted by this model, under the stress conditions (loss, noise) of the associated the TS 101 135 [4], is close to the reach required by TS 101 135 [4].

The receiver performance model for ETSI compliant HDSL-CAP is build-up from the following building blocks:

- A first order (linear) input model for the input block, specified in clause 5.1.1, that combines all imperfections (front-end noise, residual echo, equalization errors), in one virtual noise source.
- The generic CAP/QAM detection model, specified in clause 5.2.3.
- The parameter values specified in table 55.

The parameter values, used in the receiver performance model for ETSI compliant HDSL-CAP, are summarized in table 55. Parts of them are directly based on HDSL specifications. The remaining values are based on theory, followed by an iterative fit of the model to meet the ETSI reach requirements for HDSL-CAP under the associated stress conditions.

Various parameters are derived directly from the above-mentioned parameters. Their purpose is to simplify the required expression of the CAP/QAM-detection model used.

Table 55: Values for the parameters of the performance model, obtained from ETSI requirements for HDSL-CAP [4]

Model Parameter		HDSL.CAP/2	HDSL.CAP/1
SNR-Gap (effective)	G_{dB}	6,8 dB	6,8 dB
SNR-Gap in parts	G_{CAP_dB}	9,8 dB	9,8 dB
	G_{coding_dB}	5,0 dB	5,0 dB
	G_{impl_dB}	2,0 dB	2,0 dB
Receiver noise	P_{RNO_dB}	-105 dBm/Hz	-105 dBm/Hz
Data rate	f_d	2x1024 kb/s	1 x 2 048 kb/s
Line rate	f_b	1 168 kb/s	2 330 kb/s
Carrier frequency	f_c	138,30 kHz	226,33 kHz
bits per symbol	b	5	6
Summation bounds in the CAP/QAM model	N_H	+3	+3
	N_L	0	0
Derived Parameter			
Required SNR	SNR_{req}	$G \times (2^b - 1)$	$G \times (2^b - 1)$
	SNR_{req_dB}	$\approx 21,7$ dB	$\approx 24,8$ dB
Symbol rate	f_s	$f_b / b = 233,6$ kbaud	$f_b / b = 388,3$ kbaud

6.3 Receiver performance model for "SDSL"

This calculation model is capable of predicting a performance that is benchmarked against the performance requirements of an ETSI compliant SDSL modem (TS 101 524 [5]). The reach predicted by this model, under the stress conditions (loss, noise) of the associated the ETSI SDSL specification (TS 101 524 [5]) is close to the reach required by that ETSI specification. Deviations of predictions and requirements are less than 4,5 % in reach, and less than 125 m. The validity of the predicted performance holds for a wider range of stress conditions.

NOTE: These models are applicable to SDSL 16-UC-PAM at rates up to 2,312 Mb/s.

The receiver performance model for ETSI compliant SDSL is build-up from the following building blocks:

- A first order (linear) input model for the input block, specified in clause 5.1.1, that combines all imperfections (front-end noise, residual echo, equalization errors), in one virtual noise source (P_{RNO}).
- The generic PAM detection model, specified in clause 5.2.2.

- The parameter values specified in table 56.

The parameter values, used in the receiver performance model for ETSI compliant SDSL, are summarized in table 56. Some of these are directly based on SDSL specifications. The remaining values are based on theory.

Various parameters are derived from the above-mentioned parameters. Their purpose is to simplify the required expression of the PAM-detection model used.

Table 56: Values for the parameters of the performance model, obtained from ETSI requirements for SDSL [5]

Model parameter		SDSL model	
		≤ 256 kb/s	> 256 kb/s
SNR-Gap (effective)	G_{dB}	6,95 dB	6,25 dB
SNR-Gap in parts	G_{PAM_dB}	9,75 dB	9,75 dB
	G_{coding_dB}	4,4 dB	5,1 dB
	G_{impl_dB}	1,6 dB	1,6 dB
Receiver noise	P_{RNO_dB}	-140 dBm/Hz	
Data rate	f_d	192 ... 2 304 kb/s	
Line rate	f_b	$f_d + 8$ kb/s	
bits per symbol	b	3	
Summation bounds in PAM model	N_H	+1	
	N_L	-2	
Derived Parameter			
Required SNR	SNR_{req}	$G \times (2^{2b} - 1)$	
	SNR_{req_dB}	≈ 24,95 dB	≈ 24,25 dB
Symbol rate	f_s	$f_b / 3$	

6.4 Receiver performance model for "EC ADSL over POTS"

This calculation model is capable of predicting a performance that is benchmarked against the performance requirements of an ETSI compliant "EC ADSL over POTS" modem. The reach predicted by this model, under the stress conditions of the associated ETSI ADSL specification (TS 101 388 [7]), is close to the minimum reach required by that ETSI specification (TS 101 388 [7]). Deviations between the predicted reach and this "benchmark" reach are less than 100 m. The validity of the predicted performance holds for a wider range of stress conditions.

The receiver performance model for ETSI compliant "EC ADSL over POTS" is build-up from the following building blocks:

- A first order (linear) input model for the input block specified in clause 5.1.1, that combines all kinds of imperfections (front-end noise, residual echo and equalization errors), in one virtual noise source (P_{RNO}).
- The generic DMT detection model, specified in clause 5.2.4.
- The parameter values specified in table 57.

The parameter values, used in the receiver performance model for ETSI compliant "EC ADSL over POTS" modems, are summarized in table 57. Some of these are directly based on ADSL specifications. The remaining values are based on theory.

Table 57: Values for the performance parameters extracted from the ETSI performance requirements under ETSI stress conditions

Model parameter		DMT model		Remarks
		Upstream	Downstream	
SNR-Gap (effective)	G_{dB}	7,5 dB	7,5 dB	
SNR-Gap in parts	G_{DMT_dB} G_{coding_dB} G_{impl_dB}	9,75 dB 4,25 dB 2,0 dB	9,75 dB 4,25 dB 2,0 dB	
Receiver noise	P_{RNO_dB}	-120 dBm/Hz	-135 dBm/Hz	
Symbol rate	f_s f_{sd}	69/68 × 4 000 baud 4 000 baud	69/68 × 4 000 baud 4 000 baud	See clause 5.2.4
Data rate	f_d	32 ... 640 kb/s	32 ... 6 144 kb/s	These are minimum ranges only; wider ranges are usually supported
Line rate	f_{bd} f_b	$f_{bl} = f_d + 16 \times f_{sd}$ $f_{bh} = (f_d + 8 \times f_{sd}) \times 1,13$ $f_{bd} = \max(f_{bl}, f_{bh})$ $f_b = 69/68 \times f_{bd}$	$f_{bl} = f_d + 16 \times f_{sd}$ $f_{bh} = (f_d + 8 \times f_{sd}) \times 1,13$ $f_{bd} = \max(f_{bl}, f_{bh})$ $f_b = 69/68 \times f_{bd}$	See clause 5.2.4
Bits per symbol	b	f_{bd} / f_{sd}	f_{bd} / f_{sd}	
set of sub-carriers	$\{k\}$	$k \in [7:31]$	$k \in [7:63, 65:255]$	DMT tone $k = 64$ does not convey any bits because it is reserved as pilot tone.
Centre frequency location of tone k ; $k \in$ tones	f_k	$f_k = k \times \Delta f$ $\Delta f = 4,3125$ kHz	$f_k = k \times \Delta f$ $\Delta f = 4,3125$ kHz	
Bit-loading algorithm		FBL	FBL	See clause 5.2.4
Minimum bit-loading	b_{min}	2	2	Bits per tone per symbol
Maximum bit-loading	b_{max}	15	15	Bits per tone per symbol
NOTE 1: The relationship between line rate and data rate is a function of various modem settings, such as the use of trellis coding, interleaved mode, and framing parameters. The formulae in this table are a simplified model of this complex relationship.				
NOTE 2: The parameter values are for a modem in the interleaved mode.				

6.5 Receiver performance model for "FDD ADSL over POTS"

The receiver performance models for ETSI compliant "FDD ADSL over POTS" are build-up from the following building blocks:

- A first order (linear) input model for the input block specified in clause 5.1.1, that combines all kinds of imperfections (front-end noise, residual echo and equalization errors), in one virtual noise source (P_{RNO}).
- The generic DMT detection model, specified in clause 5.2.4.

This model is capable of evaluating the data rate (f_d), and uses the evaluation of the line rate (f_b) as intermediate step. In addition, the data rates (f_d) predicted by the model is to be limited to the maximum data rates (f_{d_max}) specified in table 58.

The parameter values, used in the receiver performance model for ETSI compliant "FDD ADSL over POTS" modems, are summarized in table 58. Some of these are directly based on ADSL specifications. The remaining values are extracted from ADSL performance requirements or based on theory.

Table 58: Values for the performance parameters of the ADSL receiver model

Model parameter		DMT model		Remarks
		Upstream	Downstream	
SNR-Gap (effective)	G_{dB}	9,0 dB	8,0 dB	
SNR-Gap in parts	G_{DMT_dB} G_{coding_dB} G_B G_{impl_dB}	9,75 dB 4,25 dB 3,5 dB	9,75 dB 4,25 dB 2,5 dB	
Receiver noise	P_{RNO_dB}	-120 dBm/Hz	-140 dBm/Hz	
Symbol rate	f_s f_{sd}	69/68 × 4 000baud 4 000 baud	69/68 × 4 000 baud 4 000 baud	See clause 5.2.4
Data rate	f_d f_{d_max}	32 kb/s ... f_{d_max} 800 kb/s (640 kb/s, see note 2)	32 kb/s ... f_{d_max} 8192 kb/s (6 144 kb/s, see note 2)	Limit data rate to these maxima, if model predicts higher rates
Line rate	f_{bd} f_b	$f_{bl} = f_d + 16 \times f_{sd}$ $f_{bh} = (f_d + 8 \times f_{sd}) \times 1,13$ $f_{bd} = \max(f_{bl}, f_{bh})$ $f_b = 69/68 \times f_{bd}$	$f_{bl} = f_d + 16 \times f_{sd}$ $f_{bh} = (f_d + 8 \times f_{sd}) \times 1,13$ $f_{bd} = \max(f_{bl}, f_{bh})$ $f_b = 69/68 \times f_{bd}$	See clause 5.2.4, and note 3
Bits per symbol	b	f_{bd} / f_{sd}	f_{bd} / f_{sd}	
Default set of sub-carriers, for use with "adjacent transmitter model"	{ k }	$k \in [7:31]$	$k \in [33:63, 65:255]$	DMT tone $k = 64$ does not convey any bits because it is reserved as pilot tone
Alternative set of sub-carriers, for use with "guard-band transmitter model"	{ k }	$k \in [7:31]$	$k \in [38:63, 65:255]$	DMT tone $k = 64$ does not convey any bits because it is reserved as pilot tone
Centre frequency location of sub-carrier k ; ($k \in$ sub-carriers)	f_k	$f_k = k \times \Delta f$ $\Delta f = 4,3125$ kHz	$f_k = k \times \Delta f$ $\Delta f = 4,3125$ kHz	
Bit-loading algorithm		FBL	FBL	See clause 5.3.4
Minimum bit-loading	b_{min}	1 (see note 1)	1 (see note 1)	Bits per tone per symbol
Maximum bit-loading	b_{max}	15 (see note 1, note 2, and max data rate f_{d_max})	15 (see note 1, note 2 and max data rate f_{d_max})	Data rate shall be limited to f_{d_max} if model predicts higher rates
<p>NOTE 1: The ADSL standard [8] specifies the bit-loading as integer values between 2 and 15, however the use of a model with "Fractional" bit-loading enables the use of non-integer values to account for other receiver properties as well. This enables the modelling of other receiver characteristics, as if the bit-loading caused them. Using a minimum bit-loading value of 1 instead of 2 is partially to account for absence of rounding in the FBL bit-loading and partially to account for increased bit-loading flexibility when modems operate with excess margin.</p> <p>In some cases it may be appropriate to use maximum upstream bit-loading lower than 15 in the models to account for imperfections commonly observed in real ADSL implementations.</p> <p>NOTE 2: The maximum data rate assumed for the first generation ADSL are 800 kb/s upstream and 8 192 kb/s downstream. In some cases these maximum values are limited to 640 kb/s upstream and 6 144 kb/s downstream. These limitations need to be considered when evaluating ADSL performance.</p> <p>NOTE 3: The correction factor 1.13 represents the Reed Solomon coding overhead, and is connected with the coding gain of 4,25 dB.</p> <p>NOTE 4: The relationship between line rate and data rate is a function of various modem settings, such as the use of trellis coding, interleaved mode, and framing parameters. The formulae in this table are a simplified model of this complex relationship.</p> <p>NOTE 5: The parameter values are for a modem in the interleaved mode.</p>				

6.6 Receiver performance model for "EC ADSL over ISDN"

This calculation model is capable of predicting a performance that is benchmarked against the performance requirements of an ETSI compliant "EC ADSL over ISDN" modem. The reach predicted by this model, under the stress conditions of the associated ETSI ADSL specification (TS 101 388 [7]), is close to the minimum reach required by that ETSI specification (TS 101 388 [7]). Deviations between the predicted reach and this "benchmark" reach are in most cases less than 80 m. The validity of the predicted performance holds for a wider range of stress conditions.

The receiver performance model for ETSI compliant "EC ADSL over ISDN" is build-up from the following building blocks:

- A first order (linear) input model for the input block specified in clause 5.1.1, that combines all kinds of imperfections (front-end noise, residual echo and equalization errors), in one virtual noise source (P_{RNO}).
- The generic DMT detection model, specified in clause 5.2.4.
- The parameter values specified in table 59.

The parameter values, used in the receiver performance model for ETSI compliant "EC ADSL over ISDN" modems, are summarized in table 59. Some of these are directly based on ADSL specifications. The remaining values are based on theory.

Table 59: Values for the performance parameters extracted from the ETSI performance requirements under ETSI stress conditions

Model parameter		DMT model		Remarks
		Upstream	Downstream	
SNR-Gap (effective)	G_{dB}	7,8 dB	7,5 dB	
SNR-Gap in parts	G_{DMT_dB} G_{coding_dB} G_{impl_dB}	9,75 dB 4,25 dB 2,3 dB	9,75 dB 4,25 dB 2,0 dB	
Receiver noise	P_{RNO_dB}	-120 dBm/Hz	-135 dBm/Hz	
Symbol rate	f_s f_{sd}	69/68 × 4 000 baud 4 000 baud	69/68 × 4 000 baud 4 000 baud	See clause 5.2.4
Data rate	f_d	32 ... 640 kb/s	32 ... 6 144 kb/s	These are minimum ranges only; wider ranges are usually supported
Line rate	f_{bd} f_b	$f_{bl} = f_d + 16 \times f_{sd}$ $f_{bh} = (f_d + 8 \times f_{sd}) \times 1,13$ $f_{bd} = \max(f_{bl}, f_{bh})$ $f_b = 69/68 \times f_{bd}$	$f_{bl} = f_d + 16 \times f_{sd}$ $f_{bh} = (f_d + 8 \times f_{sd}) \times 1,13$ $f_{bd} = \max(f_{bl}, f_{bh})$ $f_b = 69/68 \times f_{bd}$	See clause 5.2.4
Bits per symbol	b	f_{bd} / f_{sd}	f_{bd} / f_{sd}	
set of sub-carriers	$\{k\}$	$k \in [33:63]$	$k \in [33:95, 97:255]$ <i>Tone 96 = pilot tone</i>	<i>DMT tone k = 96 does not convey any bits because it is reserved as pilot tone.</i>
Centre frequency location of tone k; k ∈ tones	f_k	$f_k = k \times \Delta f$ $\Delta f = 4,3125$ kHz	$f_k = k \times \Delta f$ $\Delta f = 4,3125$ kHz

NOTE 1: The relationship between line rate and data rate is a function of various modem settings, such as the use of trellis coding, interleaved mode, and framing parameters. The formulae in this table are a simplified model of this complex relationship.				
NOTE 2: The parameter values are for a modem in the interleaved mode.				

6.7 Receiver performance model for “FDD ADSL over ISDN”

The downstream receiver performance model for ETSI compliant "FDD ADSL over ISDN" is build-up from the following building blocks:

- A first order (linear) input model for the input block specified in clause 5.1.1, that combines all kinds of imperfections (front-end noise, residual echo and equalization errors), in one virtual noise source (P_{RN0}).
- The generic DMT detection model, specified in clause 5.2.4.

This model is capable of evaluating the data rate (f_d), and uses the evaluation of the line rate (f_b) as intermediate step. In addition, the data rates (f_d) predicted by the model is to be limited to the maximum data rates (f_{d_max}) specified in table 60.

The parameter values, used in the receiver performance model for ETSI compliant "FDD ADSL over ISDN" modems, are summarized in table 60. Some of these are directly based on ADSL specifications. The remaining values are extracted from the ADSL performance requirements or based on theory.

Table 60: Values for the performance parameters of the ADSL receiver model

Model parameter		DMT model		Remarks
		Upstream	Downstream	
SNR-Gap (effective)	G_{dB}	8,0 dB	7,0 dB	
SNR-Gap in parts	G_{DMT_dB} G_{coding_dB} G_{impl_dB}	9,75 dB 4,25 dB 2,5 dB	9,75 dB 4,25 dB 1,5 dB	
Receiver noise	P_{RNO_dB}	-120 dBm/Hz	-140 dBm/Hz	
Symbol rate	f_s f_{sd}	69/68 × 4 000 baud 4 000 baud	69/68 × 4 000 baud 4 000 baud	See clause 5.2.4
Data rate	f_d f_{d_max}	32 kb/s ... f_{d_max} 800 kb/s (640 kb/s, see note 2)	32 kb/s ... f_{d_max} 8 192 kb/s (6 144 kb/s, see note 2)	Limit data rate to these maxima, if model predicts higher rates
Line rate	f_{bd} f_b	$f_{bl} = f_d + 16 \times f_{sd}$ $f_{bh} = (f_d + 8 \times f_{sd}) \times 1,13$ $f_{bd} = \max(f_{bl}, f_{bh})$ $f_b = 69/68 \times f_{bd}$	$f_{bl} = f_d + 16 \times f_{sd}$ $f_{bh} = (f_d + 8 \times f_{sd}) \times 1,13$ $f_{bd} = \max(f_{bl}, f_{bh})$ $f_b = 69/68 \times f_{bd}$	See clause 5.2.4 and note 3
Bits per symbol	b	f_{bd} / f_{sd}	f_{bd} / f_{sd}	
Default set of sub carriers, for use with "adjacent transmitter model"	{k}	$k \in [33:63]$ see note 4	$k \in [64:95, 97:255]$ see note 4	DMT tone $k = 96$ does not convey any bits because it is reserved as pilot tone
Alternative set of sub carriers, for use with "guard band transmitter model"	{k}	$k \in [33:56]$ see note 4	$k \in [64:95, 97:255]$ see note 4	DMT tone $k = 96$ does not convey any bits because it is reserved as pilot tone
Centre frequency location of sub-carrier k; ($k \in$ sub-carrier)	f_k	$f_k = k \times \Delta f$ $\Delta f = 4,3125$ kHz	$f_k = k \times \Delta f$ $\Delta f = 4,3125$ kHz	
Bit-loading algorithm		FBL	FBL	See clause 5.2.4
Minimum bit-loading	b_{min}	1 (see note 1)	1 (see note 1)	Bits per tone per symbol
Maximum bit-loading	b_{max}	15 (see note 1, note 2, and max data rate f_{d_max})	15 (see note 1, note 2 and max data rate f_{d_max})	Data rate shall be limited to f_{d_max} if model predicts higher rates
<p>NOTE 1: The ADSL standard [8] specifies the bit-loading as integer values between 2 and 15, however the use of a model with "Fractional" bit-loading enables the use of non-integer values to account for other receiver properties as well. This enables the modelling of other receiver characteristics, as if the bit-loading caused them. Using a minimum bit-loading value of 1 instead of 2 is partially to account for absence of rounding in the FBL bit-loading and partially to account for increased bit-loading flexibility when modems operate with excess margin.</p> <p>In some cases it may be appropriate to use maximum upstream bit-loading lower than 15 in the models to account for imperfections commonly observed in real ADSL implementations.</p> <p>NOTE 2: The maximum data rate assumed for the first generation ADSL are 800 kb/s upstream and 8 192 kb/s downstream. In some cases these maximum values are limited to 640 kb/s upstream and 6 144 kb/s downstream. These limitations need to be considered when evaluating ADSL performance.</p> <p>NOTE 3: The correction factor 1.13 represents the Reed Solomon coding overhead, and is connected with the coding gain of 4,25 dB.</p> <p>NOTE 4: The available set of tones, according to the standard, is somewhat wider and ranges for upstream $k \in [33:64]$, and for downstream $k \in [60:95, 97:255]$. However this was not intended to be used in overlap.</p> <p>NOTE 5: The relationship between line rate and data rate is a function of various modem settings, such as the use of trellis coding, interleaved mode, and framing parameters. The formulae in this table are a simplified model of this complex relationship.</p> <p>NOTE 6: The parameter values are for a modem in the interleaved mode.</p>				

6.8 Receiver performance model for "VDSL"

NOTE: This model is left for further study.

7 Transmission and reflection models

7.1 Summary of test loop models

Over the years, a variety of two-port models have been extracted from cable measurements up to 30 MHz, and published in several documents. These models are so numerous due to the wide range of cables being used in different countries.

An example of a two-port models of a 100 Ω cable and of a 150 Ω cable can be found in the VDSL (TS 101 270-1 [11], annex A).

NOTE: Other examples of two-port cable models can be found in ETSI specifications for SDSL (TS 101 524 [5]) and ADSL (TS 101 388 [7]), however they are not defined up to the full 30 MHz band.

8 Crosstalk models

Crosstalk is commonly a dominant contributor to the overall disturbance that impairs a transmission. Crosstalk models are to evaluate how much crosstalk originates from various disturbers that are distributed over the local loop wiring. In practice this is not restricted to a one-dimensional cable topology, since wires may fan out into different directions to connect for instance different customers to a central office.

This clause summarizes basic models for evaluating crosstalk in various scenarios. The models are presented here as individual building blocks, but a full analysis requires the use of a combination of these blocks.

8.1 Basic models for crosstalk cumulation

Cumulation models relate the crosstalk powers generated by multiple disturbers with the *number* and *type* of these disturbers.

The meaning of *the* crosstalk power is not obvious. When a cable with N wire pairs is filled-up completely with similar disturbers, the resulting crosstalk power in each wire-pair (from $N-1$ disturbers connected to the other wire-pairs) is maximal and therefore unambiguous. This upper limit is the saturated crosstalk power for that type of disturber, for that particular wire-pair.

However if the number M of disturbers is lower ($M < N-1$), this crosstalk power will commonly change when another combination of M wire-pairs will be chosen. So an exact expression for the resulting crosstalk, as function of the *number* and *type* of disturbers, does not exist if it remains unknown to which wire-pairs they are connected.

What does exist are crosstalk powers that occur with a certain probability. To illustrate that, consider an experiment that connects 30 disturbers to a cable with 100 wire pairs in 100.000 different ways. If the resulting noise is observed in one particular wire-pair, it is most likely that 100.000 different crosstalk noise powers will be observed. The result of such a "probability experiment" is therefore not a single power, but a (wide) range of powers with a certain probability distribution.

Within this range, a certain crosstalk noise power can be found that is not exceeded in 99% of the cases (or 80% or 65% or whatsoever). That power level is named a *probability limit* for a particular wire pair.

A cumulation model predicts how such a *limit* (at given probability) behaves as a function of number and type of disturbers. The use of 99% worst case limits is commonly used. When a study evaluates the performance under a noise power that equals such a probability limit, then the actual performance will in "most cases" be better then predicted in this way. The use of 100% worst case limits is commonly avoided, to prevent for over-pessimistic analyses.

8.1.1 Uniform cumulation model

The uniform cumulation model is restricted to the special case that all disturbers are from the same type. It assumes that the probability limit from M disturbers is proportional with M^{1/K_n} , where K_n is an empirical parameter (values like $K_n=1/0,6$ are commonly used for 99% worst case analyses).

Expression 14 shows this uniform cumulation model. It uses a frequency dependent quantity P_{Xd} (the *normalized crosstalk power*) as intermediate result, that has been derived from the saturated crosstalk power (maximum cross talk power at 100% cable fill), for that particular type of disturber.

This saturated crosstalk power will most likely be different for each individual wire-pair, but a worst case value of all wire-pairs could be selected if a cable is to be modelled as a whole. Hence Expression 1 can be applied to predict probability limits in either a single wire-pair or in a cable as a whole. The difference is that in the latter case $P_X(N-1, f)$ is the saturated crosstalk power in the worst-case wire-pair (having the highest saturated value) and that $P_X(M, f)$ represents a statistical value (e.g. a 99% worst case value) taken from much more values than in the single wire-pair case.

The reliability of the model improves when $M \gg 1$. By definition, the model provides an exact value for the crosstalk power experienced within a specific victim wire-pair when $M=(N-1)$.

$P_X(M, f) = M^{1/K_n} \times P_{Xd}(f) \quad \text{with } P_{Xd}(f) \stackrel{\text{def}}{=} \frac{P_X(N-1, f)}{(N-1)^{1/K_n}}$	
N M $P_X(M, f)$ $P_X(N-1, f)$ $P_{Xd}(f)$ K_n f	= number of wire pairs in the cable = number of similar disturbers ($1 \leq M \leq N-1$) = probability limit of crosstalk from M similar disturbers = saturated crosstalk power (at a complete cable fill) = normalized crosstalk power, for that particular disturber type = empirical constant ($K_n=1/0,6$ is commonly used) = frequency

Expression 14: Definition of the uniform cumulation model

NOTE: For some cables used in the Netherlands, it has been observed that a slightly different value for K_n provides a better fit with measurements on these cables. For instance, values between 1/0,6 and 1/0,8 have been observed. For those cables, these values for K_n may be more appropriate for use in expression 14 and associated expressions.

8.1.2 FSAN sum for crosstalk cumulation

The FSAN sum is a cumulation model that is also applicable when different disturbers are involved. It is a generalization of the uniform cumulation model, and is specified in expression 15. The (frequency dependent) probability limit of the crosstalk, caused by M individual disturbers, is expressed below.

$P_X(M, f) = \left(P_{Xd,1}(f)^{K_n} + P_{Xd,2}(f)^{K_n} + P_{Xd,3}(f)^{K_n} + \mathbf{L} + P_{Xd,M}(f)^{K_n} \right)^{1/K_n}, \quad \text{with } K_n = \frac{1}{0,6}$	
M $P_X(M, f)$ $P_{Xd,k}(f)$ K_n f	= number of involved disturbers = probability limit of crosstalk from those M disturbers = normalized crosstalk power, for disturber k , as defined in expression 14. = empirical constant ($K_n=1/0,6$ is used for the FSAN sum) = frequency

Expression 15: FSAN sum for cumulating the power levels of M individual disturbers into the power level of an equivalent disturber

Factor K_n is assumed to be frequency independent. In the special case that all M disturbers generates equal power levels (P_{Xd}) at all frequencies of interest, the FSAN sum simplifies into $P_X(M, f) = P_{Xd}(f) \times M^{1/K_n}$. This demonstrates consistency with the uniform cumulation model.

The FSAN sum operates directly on powers, and ignores the existence of source and termination impedances. If different impedances are involved (due to different disturber and victim types), their *available* power levels are to be combined according to the FSAN sum. Available power of a source is the power dissipated in a load resistance, equal to its source impedance.

8.2 Basic models for NEXT and FEXT coupling

These sub-models for crosstalk coupling are to evaluate the normalized crosstalk power, as defined before in expression 14, that a single disturbing modem pair couples into a specific (other) wire-pair in the cable. However, it should be noted that the models in this clause are restricted to *normalized* crosstalk coupling only, and are not intended for evaluating the *actual* crosstalk coupling between two individual wire-pairs. The actual coupling fluctuates rapidly with the frequency and changes significantly per wire-pair combination. Therefore the ratio between *normalized* crosstalk amplitude (measured at 100% cable fill, and subsequently normalized to a single disturber) and the disturber amplitude is being modeled.

The models for topologies with multiple disturber pairs are derived from these basic models.

- NEXT-coupling refers to the transfer function between ends of different pairs at the same cable section side (“near-end”).
- FEXT-coupling refers to the transfer function between ends of different pairs at the opposite cable section sides (“far-end”).

When P_d represents the (frequency dependent) transmit power of the involved disturber, and P_{Xd} represents the (frequency dependent) normalized crosstalk power (scaled down from the saturated crosstalk power at 100% cable fill), then this ratio becomes as shown below in expression 16:

$$H(f) = \text{normalized crosstalk coupling} = \sqrt{\frac{\text{normalized crosstalk power}}{\text{disturber power}}} = \sqrt{\frac{P_{Xd}(f)}{P_d(f)}}$$

Expression 16: Definition of normalized crosstalk coupling function.

The normalized crosstalk coupling is dependent from the wire-pair being connected to the victim modem pair. A possible approach for modeling coupling in cables as a *whole*, is to find the normalized crosstalk power (for a chosen disturber type) in each of the N wire pairs of the cable, and then to find (for each frequency) the 99% worst case value of those N powers.

8.2.1 Normalized NEXT and FEXT coupling at an elementary cable section

The normalized coupling models for co-located NEXT and FEXT are restricted to the special case of an elementary cable section topology, as illustrated in figure 10. The LT side of a disturbing modem pair is in such a topology co-located with the LT-side of a victim modem, and the same applies to the NT side. It means that the two involved wire-pairs are coupled over the full length of that (elementary) cable or cable section.

Figure 10: Example of a two-node cable section topology

Expression 17 specifies the transfer functions of this normalized NEXT and FEXT coupling model. The termination impedances of the wire-pairs are fully ignored in this model, and all wire-pairs are assumed to be terminated by the *characteristic* impedance Z_0 of the cable. By doing so, a cascade of two loops can easily be evaluated by multiplying their respective characteristic transmissions, without bothering impedances.

$H_{next}(f, L) = K_{xn} \times \left(\frac{f}{f_0} \right)^{0,75} \times \sqrt{1 - s_T(f, L) ^4}$ $H_{fext}(f, L) = K_{xf} \times \left(\frac{f}{f_0} \right) \times \sqrt{L/L_0} \times s_T(f, L) $
<p>NOTE 1: Parameter f refers to the frequency. Constant f_0 identifies a chosen reference frequency, commonly set to $f_0 = 1$ MHz.</p> <p>NOTE 2: Parameter L refers to the coupling length of the wirepairs. Constant L_0 identifies a chosen reference length, commonly set to $L_0 = 1$ km.</p> <p>NOTE 3: Values for K_{xn} and K_{xf} are cable specific, and are to be specified for each scenario being studied. Commonly used values (in dB) for generic European studies, not dedicated to any particular cable or region, are: $K_{xn_dB} = -50$ dB and $K_{xf_dB} = -45$ dB for $f_0 = 1$ MHz and $L_0 = 1$ km.</p> <p>NOTE 4: Function $s_T(f, L)$ represents the frequency and length dependent characteristic transmission of the wire pairs. This equals the insertion loss when the cable is terminated at both ends with its characteristic impedance.</p>

Expression 17: Transfer functions of co-located normalized NEXT and FEXT coupling

8.2.2 Normalized NEXT and FEXT coupling at distributed or branched cables

When crosstalk from a disturbing modem pair originates from locations that are not co-located with the victim modem pair, the two involved wire-pairs are not coupled over the full length. An example topology occurs when a victim modem-pair operates between cabinet and customer premises while a disturbing modem pair operates between central office and customer premises. Another example topology occurs when a cable is branched to different (customer) locations, from a certain point in the loop. Both examples are illustrated in figure 11.

Figure 11: Two example topologies with branching

In all these distributed or branched examples, the interaction between disturbers and victims can be characterized by a common section that couples signals, and four independent sections (branches) that are attenuating signals only. This is illustrated in figure 12. Branches may have zero length in special topologies.

Figure 12: Example of the lengths that are to be used for evaluating branched normalized NEXT and FEXT

The expressions for branched normalized crosstalk coupling are not so different from the co-located case. They mainly differ by the fact that *two* length values are involved instead of one: the coupling length L_C and the total branch length L_B . The branched model is simply derived from the co-located model, by incorporating the additional attenuation of these branches.

The table in figure 12 summarizes what the total branch length is for each combination of ports. The associated transfer functions from a disturbing transmitter to a victim modem are shown in expression 18. If $L_B=0$, the expressions simplify in those for the co-located case, and this demonstrates consistency between the two models.

This model assumes a single cable type, so that branch length could be added to the coupling length to account for its insertion loss. If this is not the case, the insertion losses of the branches have to be evaluated individually.

$$\begin{aligned}
 H_{next}(f, L_C, L_B) &= K_{xn} \times \left(\frac{f}{f_0} \right)^{0,75} \times \sqrt{1 - |s_T(f, L_C)|^4} \times |s_T(f, L_B)| \\
 H_{fext}(f, L_C, L_B) &= K_{xf} \times \left(\frac{f}{f_0} \right) \times \sqrt{L_C / L_0} \times |s_T(f, L_C + L_B)|
 \end{aligned}$$

NOTE 1: Parameter f refers to the frequency.
Constant f_0 identifies a chosen reference frequency, commonly set to $f_0 = 1$ MHz.

NOTE 2: Parameter L_C refers to the coupling length between the wire pair connected to the disturbing transmitter and the wire pair connected to the victim receiver. It represents the length they share in the same cable.
Constant L_0 identifies a chosen reference length, commonly set to $L_0 = 1$ km.

NOTE 3: Parameter L_B refers to the respective branching length (for adding signal attenuation only) from a disturbing transmitter to a victim receiver.

NOTE 4: Values for K_{xn} and K_{xf} are cable specific, and are to be specified for each scenario being studied. Commonly used values (in dB) for generic European studies, not dedicated to any particular cable or region, are: $K_{xn_dB} = -50$ dB and $K_{xf_dB} = -45$ dB for $f_0 = 1$ MHz and $L_0 = 1$ km.

NOTE 5: Function $s_T(f, L)$ represents the frequency and length dependent characteristic transmission of the wire pairs. This would be the insertion loss when the cable is terminated at both ends with its characteristic impedance.

Expression 18: Transfer functions of branched normalized NEXT and FEXT coupling

8.3 Basic models for crosstalk injection

These sub-models are applicable to studies where the noise level has to be adjusted for impedance mismatch. When the impedance of the victim modem changes, the noise (and signal) observed by the receiver will change as well. To account for this effect, a crosstalk injection block can be included in a topology models.

The transfer function of the crosstalk injection block identified as H_{xi} , and is frequency and impedance dependent. Expression 19 illustrates how to use this transfer function for evaluating the power level P_{RN} from power level P_{XN} .

$$P_{RN} = P_{XN} \times |H_{xi}|^2$$

Expression 19: Evaluation of the receive noise level from the crosstalk noise level under matched conditions, by a transfer function of the noise injector

A transfer function that models the impact of impedance mismatch can be very complex, and therefore several simplified transfer functions are commonly used to approximate this effect. This clause summarizes a few of these approximations.

8.3.1 Forced noise injection

When crosstalk injection is modelled by means of *forced* noise injection, then all impedance and frequency dependency of noise injection is ignored. The associated transfer function is shown in expression 20.

$$H_{xi}(f) = 1$$

Expression 20: Transfer function for forced noise injection.

8.3.2 Current noise injection

When crosstalk injection is modelled by means of *current* noise injection, then it is assumed that the impedance dependency can be represented by the equivalent circuit diagram shown in figure 13. The associated transfer function is shown in expression 21.

- The *injection condition* holds when the performance is evaluated. Impedance Z_{LX} represents the cable with its terminating impedance at the other ends of the line. Z_{LX} is usually a frequency dependent and complex impedance.
- The *calibration condition* holds for the situation that noise has been evaluated. Z_{cal} should be a well-defined impedance. This can be a complex artificial impedance approximating Z_{LX} , or simply a fixed real impedance. In the special case that $Z_{cal} \equiv Z_{LX}$, the concept of "current injection" simplifies into "forced injection" as described in the previous clause.

Figure 13: Current injection enables modelling of the impedance dependent behaviour of crosstalk noise levels

The transfer function $H_{xi}(f) = (U_i/U_c)$ between (a) the signal voltage U_i over impedance R_V during injection condition, and (b) U_c during calibration condition, equals:

$$H_{xi}(f, Z_{LX}) = \left(\frac{1/Z_{cal} + 1/Z_{inj} + 1/R_V}{1/Z_{LX} + 1/Z_{inj} + 1/R_V} \right)$$

Expression 21: Transfer function to model impedance dependency according to the current injection method

8.4 Overview of different network topologies

The results of spectral management studies are highly dependent on the chosen network topology, which is very country and location specific. The most simple topology models assume that all disturbers are co-located at only two locations; one at each end of a cable. This approximation is computational convenient but is generally inadequate to represent the real world. For example it will conceal effects due to fan out of the wires (relevant for short loops), and due to secondary NEXT.

More advanced topology models require a multi-node co-location approach. An example is the insertion of repeaters that introduces co-located disturbers in-between. Another example is deploying VDSL from the cabinet for the situation that all customers are distributed along the cable. It is recommended to use a multi-node approach, because this makes the simulation more realistic. A two-node approach implies that all NT disturbers are virtually co-located, and this is too pessimistic. This may cause pessimistic downstream results.

In practice topologies are not restricted to a linear cable topology, since wires may fan out into different directions to connect for instance different customers to a central office. This requires a branched multi-node approach. In the current version of the present document, only the most simple topology (with two nodes) has been elaborated, while the description of more advanced topology models is left for further study.

8.5 Crosstalk evaluation for multi-node topologies

If a victim modem pair is impaired by disturbers from all kinds of locations, the evaluation of the crosstalk probability limits may be rather complex. Figure 14 shows an example of the wiring in a multi-node topology.

Figure 14: Example of the wiring in a multi-node topology.

Essentially, this example with five wire pairs is a combination of four individual couplings between a disturbing modem pair and the victim modem pair. Each coupling function can be different (in coupling length, in branching length, etc). By evaluating these individual coupling functions one by one, the probability limits of the crosstalk from all involved disturbers can be derived.

The probability limit $P_{XN,NT}$ of the crosstalk power at the NT side of a victim modem pair, and the associated probability limit $P_{XN,LT}$ at the other side, can be evaluated as follows:

- First, evaluate for each individual disturber pair $\{k\}$, the four normalized crosstalk coupling functions between the two disturbers and the two victims. Appropriated models are provided in expression 18. When disturbers are not co-located with other disturbers, the coupling and branching lengths may be different for each disturber pair.
- Then, evaluate for each individual disturber pair $\{k\}$ the normalized crosstalk power $P_{Xd\{k\}}$ from the transmit power $P_{d\{k\}}$ of the involved disturber. This is formulated below at both victim modems:

Normalized NEXT at NT-side:	$P_{XN,d\{k\},NT} = P_{d\{k\},NT} \times H_{next\{k\},NT} ^2$
Normalized NEXT at LT-side:	$P_{XN,d\{k\},LT} = P_{d\{k\},LT} \times H_{next\{k\},LT} ^2$
Normalized FEXT at NT-side:	$P_{XF,d\{k\},NT} = P_{d\{k\},LT} \times H_{fext\{k\},NT} ^2$
Normalized FEXT at LT-side:	$P_{XF,d\{k\},LT} = P_{d\{k\},NT} \times H_{fext\{k\},LT} ^2$
- Next, cumulate all these normalized individual NEXT powers with an appropriated cumulation model (for instance the FSAN sum in expression 15) into a probability limit of the NEXT.
- Do the same for normalized FEXT powers.
- Finally add both powers. If direct disturbers ($P_{bn,NT}$ and $P_{bn,LT}$) are also involved (like systems sharing the same wire pair in another frequency band), then they can be added here as well.

Expression 22 evaluates the probability limit of the crosstalk at each receiver as explained above, in the case that FSAN summing is applied for the cumulation, and direct disturbers are involved at both sides.

$$P_{XN,NT} = \left(\sum_{k=1}^M \left(P_{d\{k\},NT} \times |H_{next\{k\},NT}|^2 \right)^{Kn} \right)^{1/Kn} + \left(\sum_{k=1}^M \left(P_{d\{k\},LT} \times |H_{fext\{k\},LT}|^2 \right)^{Kn} \right)^{1/Kn} + P_{bn,NT}$$

$$P_{XN,LT} = \left(\sum_{k=1}^M \left(P_{d\{k\},LT} \times |H_{next\{k\},LT}|^2 \right)^{Kn} \right)^{1/Kn} + \left(\sum_{k=1}^M \left(P_{d\{k\},NT} \times |H_{fext\{k\},NT}|^2 \right)^{Kn} \right)^{1/Kn} + P_{bn,LT}$$

NOTE1: Power $P_{d\{k\}}$ represents the transmit power of an involved disturber k , and M represents the total number of involved disturbers in the cable.

NOTE2: All involved powers P and coupling functions H are assumed to be frequency dependent, but this has been omitted to simplify the above expressions.

Expression 22: Evaluation of the probability limit of the crosstalk at each receiver

8.6 Crosstalk evaluation for two-node topologies

In the special (simplified) case that all disturbers are co-located with one of the two victim modems, the generalized approach in expression 22 can be simplified significantly. Such an approach can be applicable to scenarios with long distribution cables in which all customers can be regarded as virtually co-located (compared to the length of the distribution cable). Since they are all served from the same central office, the topology requires only two nodes (one on the LT side, and another one on the "common" NT side).

Figure 15 shows an example of the wiring in such a two-node topology.

Figure 15: Example of the wiring in a two-node topology, where all wire-pairs are assumed to be of equal length.

An additional characteristic of two-node topologies is that all the NEXT coupling functions in expression 22 are assumed equal, and that the same applies for the FEXT coupling functions. The result is that the previous expression 22 for crosstalk simplifies into expression 23. By combining the powers $P_{d\{k\}}$ from all co-located disturbers into a single equivalent disturber $P_{d,eq}$ at that location, the crosstalk expression simplifies even further as shown in expression 24.

$$P_{XN,NT} = \left(\sum_k (P_{d\{k\},NT})^{Kn} \right)^{1/Kn} \times |H_{next}|^2 + \left(\sum_k (P_{d\{k\},LT})^{Kn} \right)^{1/Kn} \times |H_{fext}|^2 + P_{bn,NT}$$

$$P_{XN,LT} = \left(\sum_k (P_{d\{k\},LT})^{Kn} \right)^{1/Kn} \times |H_{next}|^2 + \left(\sum_k (P_{d\{k\},NT})^{Kn} \right)^{1/Kn} \times |H_{fext}|^2 + P_{bn,LT}$$

Expression 23 Simplified version of expression 22, for the special case that all NEXT and all FEXT couplings are the same

$P_{d,eq} \stackrel{def}{=} \left(\sum_k (P_{d\{k\}})^{Kn} \right)^{1/Kn} \quad (\text{for each end of the cable})$
$P_{XN,NT} = P_{d,eq,NT} \times H_{next} ^2 + P_{d,eq,LT} \times H_{fext} ^2 + P_{bn,NT}$
$P_{XN,LT} = P_{d,eq,LT} \times H_{next} ^2 + P_{d,eq,NT} \times H_{fext} ^2 + P_{bn,LT}$
<p>NOTE All involved powers P and coupling functions H are assumed to be frequency dependent, but this has been omitted for simplifying the above expressions.</p>

Expression 24: Evaluation of the crosstalk from two locations.

A convenient way of presenting the evaluation of the various crosstalk powers is the use of a flow diagram. This is shown in figure 16 (for downstream) and 17 (for upstream) for the two-node topology. It illustrates how the various building blocks of expression 24 work together when deriving the probability limits of the crosstalk.

The flow diagram illustrates that the crosstalk can be evaluated in steps.

- The diagram combines for each end of the cable the disturber output powers (P_{d1}, P_{d2}, \dots) into a single equivalent disturber ($P_{d,eq}$), as if the cumulation operates directly on these disturber powers. This has been illustrated in figures 16 and 17 by a box drawn around the involved building blocks. Using the equivalent disturber concept as intermediate result yields an elegant concept to break down the complexity of a full noise scenario into smaller pieces, but works only for two-node topologies.
- Next, the diagram evaluates the probability limit of the crosstalk noise (P_{XN}), that is coupled into the wire pair of the victim modem being studied. Figures 16 and 17 illustrate what portion of the equivalent disturbance is coupled into that wire pair by using models for (co-located) normalized NEXT and FEXT.
- If direct disturbers are involved, their power (P_{bn}) can be added to the probability limit of the crosstalk noise. Such a direct disturber can be used to represent for instance (a) line shared noise (from POTS/ISDN to ADSL), (b) all kinds of unidentified (“background”) noise sources or (c) anything else not being incorporated in the NEXT and FEXT coupling models.

Since it is a generic diagram, the power of this direct noise is left undefined here. Commonly used values are zero, or powers as low as $P_{bn} = -140$ dBm/Hz.

Mark that the impedance of each disturber is fully ignored in this evaluation of the crosstalk. In practice however, the impedance of a victim modem may be different for different types of victim modems. This is not as unrealistic as it may look at a first glance. When the received noise power is assumed to remain at constant level, and when the impedance of the victim modem drops, then the received noise voltage drops too. The same applies for the received signal, and this causes that the resulting changes in received signal-to-noise ratio are significantly lower. The noise injection model can be used to improve this even further, by introducing an additional impedance-dependency.

Figure 16: Flow diagram to evaluate crosstalk probability limits for two-node topologies, at the NT side (for evaluating downstream performance)

Figure 17: Flow diagram to evaluate the crosstalk probability limits for two-node topologies, at the LT side (for evaluating upstream performance)

9 Examples of evaluating various scenarios

This clause summarizes examples to show how the models in the present document can be used to perform spectral management studies.

9.1 European Spectral Platform 2004 (ESP/2004)

In 2004 several European operators created a simulation platform to support spectral management studies on e-SDSL and ADL-64. This platform comprises of several (theoretical) scenarios to cover a wide range of situations being identified in European access networks. Each scenario is a compromise between computational convenience and computational complexity of real access networks. Nevertheless, the calculated performances of xDSL systems operating under these theoretical scenarios are assumed to be indicative for the minimum performance of these systems in various European situations.

The scenarios are a combination of a technology mix (to create a noise environment), system models, topology models and loop models.

9.1.1 Technology mixtures within ESP/2004

A distinct number of technology mixtures have been identified to enable a reasonable representation of scenarios that are being deployed in various European Networks. Their names are specified in table 61.

Table 61: Naming convention of used mixtures

Name	Description of the mix
	<i>High penetration mixtures</i>
HP/M	Mix includes both ADSL FDD flavours, SDSL, VDSL, HDSL.CAP/2 and HDSL.2B1Q/2
HP/R	Mix includes all four ADSL (FDD and EC) flavors, SDSL, VDSL and HDSL.CAP/2
	<i>Medium penetration mixtures</i>
MP/M	Mix includes both ADSL FDD flavours, SDSL, VDSL and HDSL.2B1Q/2
MP/P	Mix includes ADSL over POTS FDD, SDSL, VDSL and HDSL.2B1Q/2
MP/I	Mix includes ADSL over ISDN FDD, SDSL, VDSL and HDSL.2B1Q/2

The number of systems of each technology to be considered in each scenario is specified in table 62.

- For each reference scenario, the associated reference mix is specified in the columns labelled as "ref".
- For each modified scenario, the associated modified mix is specified in the columns labelled as "mod". The number of wire pairs occupied by the broadband systems remains the same as for the reference scenario.

By comparing the change in performance between both scenarios, the impact of replacing some "legacy" systems by systems of the new technology can be visualized. This concept is referred to as the "reference method".

NOTE: The victim system shall not be considered among the disturbers, i.e. it shall be subtracted from the total number of disturbing systems. For two-pairs HDSL systems, only one pair shall be considered as victim, whereas the other one shall be kept among the disturbers.

Table 62: Reference mixtures and modified mixtures with the new technology for the five scenarios

System	Mix	HP/M		HP/R		MP/M		MP/P		MP/I	
		Ref.	Mod.	Ref.	Mod.	Ref.	Mod.	Ref.	Mod.	Ref.	Mod.
SDSL 1024 kb/s		5	5	16	16	4	4	4	4	4	4
SDSL 2048 kb/s		10	10	16	16	5	5	5	5	5	5
HDSL 2B1Q/2		3x2	2x2	-	-	1x2	0x2	1x2	1x2	1x2	1x2
HDSL CAP/2		2x2	2x2	3x2	3x2	-	-	-	-	-	-
ADSL over POTS FDD		75	68	63	55	18	16	25	20	-	-
ADSL over ISDN FDD		25	22	96	84	7	6	-	-	25	20
ADSL over POTS EC		-	-	21	19	-	-	-	-	-	-
ADSL over ISDN EC		-	-	32	29	-	-	-	-	-	-
VDSL (FTTEx)		12 ¹⁾	12 ¹⁾	25 ²⁾	25 ²⁾	5 ¹⁾	5 ¹⁾	5 ¹⁾	5 ¹⁾	5 ³⁾	5 ³⁾
New system under study		0	12	0	25	0	5	0	5	0	5
ISDN.2B1Q (alone)		50	53	97	103	14	15	14	14	0	0
ISDN.2B1Q/filtered ⁶⁾		25 ⁴⁾	22	53 ⁴⁾	48 ⁴⁾	7 ⁴⁾	6 ⁴⁾	0	0	0	0
ISDN.MMS43 (alone)		0	0	0	0	0	0	0	0	14	19
ISDN.MMS43/filtered ⁶⁾		0	0	0	0	0	0	0	0	30 ⁵⁾	30 ⁵⁾
Pairs in total for BB		137	137	275	275	41	41	41	41	41	41
Pairs in total for BB and ISDN		187	190	372	378	55	56	55	55	55	60

NOTE 1: VDSL (FTTEx) P2 M2 with US0, ETSI main plan (997) or optional regional band plan (998).
NOTE 2: VDSL (FTTEx) P2 M2 with US0, ETSI main plan (997) only.
NOTE 3: VDSL (FTTEx) P1 M1 without US0, ETSI main plan (998) only.
NOTE 4: These ISDN/2B1Q systems share the same pair with ADSL over ISDN systems.
NOTE 5: These ISDN/MMS43 systems share the same pair with ADSL or VDSL over ISDN systems.
NOTE 6: In case the victim modem shares the line with ISDN, reduce the number of filtered ISDN disturbers by one, and add a "Line shared ISDN" model to the line of that victim modem.

NOTE 1: When VDSL is considered as disturbing system for the other systems it is not necessary to specify its band plan. When making simulations on VDSL performance instead, a homogeneous VDSL environment and the band plan indicated in the explanations of table 62 should be considered.

NOTE 2: The modified mixtures depend on the type of system under study. In this example the modified mixtures were determined for studies of ADL-64 and E-SDSL.

9.1.2 System models within ESP/2004

Table 63 specifies transmitter signal models for each system being part of the mix. Power back-off or power cut-back shall be taken into account for all the systems for which it is mandatory in the relevant specification. Concerning VDSL UPBO, use the reference PSD for Noise D (see TS 101 270-1 [11]) in high penetration scenarios (using HP/M and HP/R) and the one for Noise E in medium penetration scenarios (using MP/P, MP/I and MP/M).

Table 64 specifies receiver performance models for each system being part of the mix.

Table 63: Transmitter signal models

Name	Transmitter signal model
SDSL 1024 kb/s	SDSL transmitter model, as specified in clause 4.10 for 1 024 kb/s
SDSL 2048 kb/s	SDSL transmitter model, as specified in clause 4.10 for 2 048 kb/s
HDSL 2B1Q/2	HDSL transmitter model, as specified in clause 4.8 (use " default" model)
HDSL CAP/2	HDSL transmitter model, as specified in clause 4.9
ADSL over POTS FDD	ADSL transmitter model, as specified in clause 4.12 (<i>see note</i>)
ADSL over ISDN FDD	ADSL transmitter model, as specified in clause 4.14 (<i>see note</i>)
ADSL over POTS EC	ADSL transmitter model, as specified in clause 4.11
ADSL over ISDN EC	ADSL transmitter model, as specified in clause 4.13
VDSL (FTTEx)	VDSL transmitter model, as specified in clause 4.17
ISDN.2B1Q - alone	ISDN transmitter models, as specified in clause 4.2
ISDN.2B1Q/filtered	ISDN transmitter models, as specified in clause 4.3
ISDN.2B1Q - same pair	ISDN transmitter models, as specified in clause 4.4
ISDN.MMS43 - alone	ISDN transmitter models, as specified in clause 4.5
ISDN.MMS43/filtered	ISDN transmitter models, as specified in clause 4.6
ISDN.MMS43 - same pair	ISDN transmitter models, as specified in clause 4.4
NOTE:	Use the ADSL adjacent FDD template when ADSL is considered a disturber (in the noise), but use the ADSL guardband FDD template when ADSL is considered a victim.

Table 64: Receiver performance models

Name	Receiver performance model
SDSL	SDSL receiver model, as specified in clause 6.3
HDSL 2B1Q/2	HDSL receiver model, as specified in clause 6.1
HDSL CAP/2	HDSL receiver model, as specified in clause 6.2
ADSL over POTS FDD	ADSL receiver model, as specified in clause 6.5
ADSL over ISDN FDD	ADSL receiver model, as specified in clause 6.7
ADSL over POTS EC	ADSL receiver model, as specified in clause 6.4
ADSL over ISDN EC	ADSL receiver model, as specified in clause 6.6
VDSL (FTTEx)	<i>See note</i>
ISDN.2B1Q	<i>See note</i>
ISDN.MMS43	<i>See note</i>
NOTE:	The evaluation of the performance of this victim system is no part of ESP/2004; only broadband systems were investigated as victim system.

9.1.3 Topology models within ESP/2004

The scenario assumes that an uninterrupted homogeneous cable, without branches, interconnects the victim system under study. In addition, it assumes that the network topology can be represented by a simple (point-to-point) two-node topology model (see clause 8.5).

This is of course an over-simplification of real access networks, and therefore the way systems are disturbing each other is refined (a) according to the way NT systems are distributed along the cable, and (b) to what distance NT systems are separated from their LT counterpart.

Refinements of disturbance

For the first refinement, two different topologies are defined:

- ***Distributed topology***. Here it is assumed that the NT ports of a cable (or bundle or binder group) are distributed along the loop, and that a single cable is capable of providing access to customers at both near and far distances from the exchange.
- ***Virtually co-located topology***. Here it is assumed that the NT ports of a cable (or bundle or binder group) are virtually co-located, and that a single cable can only provide access to near locations or to far locations. Different cables are then needed to connect customers at both locations.

In either case, the LT disturbers are co-located with the LT victim. To compensate for the fact that some NT disturbers are not always at the same location as the NT victim system, the crosstalk of these disturbers is attenuated first.

Attenuated crosstalk means within this context the following: Assume that no disturber resides beyond the victim NT. If L is the distance between an investigated NT victim and a group of co-located NT disturbers, then calculate the crosstalk of these disturbers (NEXT & FEXT) at the location of these disturbers as if no other disturber does exist. In the following step, attenuate this noise level by the loss of a loop with length L . Repeat this for each group of co-located NT disturbers, and subsequently add the powers of all these crosstalk components to evaluate the crosstalk level at the location of the victims.

For the second refinement, the reach limits of the involved systems are accounting for the disturbance of such a system. This means that a system will not be deployed beyond its reach limits, and that the composition of the disturber mix changes when the loop length exceeds certain reach boundaries.

To simplify this refinement, only five reach boundaries are distinguished, and the involved systems are all classified according to these boundaries. This is summarized in table 65, and illustrated in figure 18.

Table 65: System classification according to the boundaries in figure 18

System class	System examples	Deployment practice
1	VDSL	<i>VDSL will not be deployed beyond area 1 limit.</i>
2	SDSL, 2 048 kb/s	<i>2 048 kb/s SDSL will not be deployed beyond area 2 limits.</i>
3	HDSL/2	<i>Two-pair HDSL will not be deployed beyond area 3 limits, (except for "virtually co-located topologies" where the use of a regenerator is assumed to extent the reach).</i>
4	SDSL, 1 024 kb/s	<i>1 024 kb/s SDSL will not be deployed beyond area 4 limits. (except for "virtually co-located topologies" where the use of a regenerator is assumed to extent the reach).</i>
5	ADSL ISDN (SDSL, 512 kb/s)	<i>All these systems in the mix will be deployment up to area 5. (except for the "distributed topologies", that do not include 512 kb/s SDSL systems).</i>

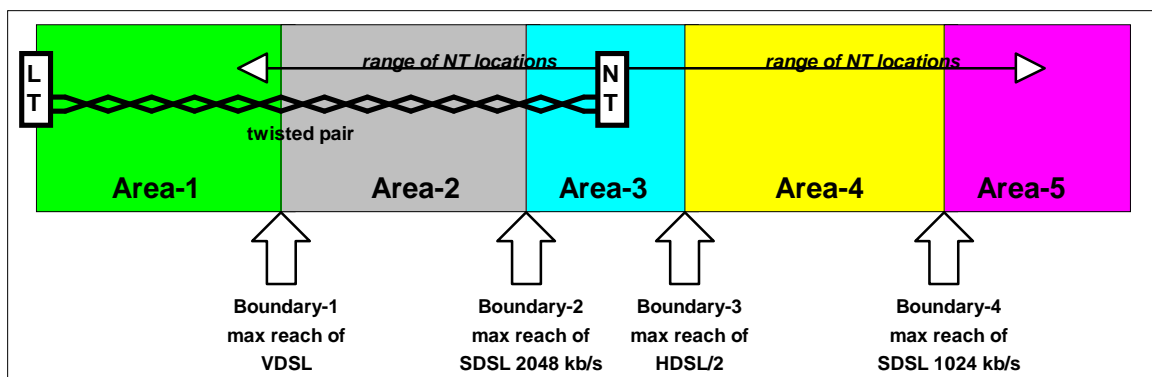

Figure 18: Concept of reach areas in ESP/2004, and associated boundaries

Boundary locations of the disturbers

The location of each boundary between two areas in figure 18 is scenario dependent, and is specified in table 66. Not all combinations of system mixtures and topology models are required for the ESP/2004 scenarios, and therefore table 66 is restricted to those combinations.

An example of the boundary values are summarized in table 66. These boundary values are assumed to be a fair reach estimation of the associated victim system, under the stress conditions of that particular scenario. Due to minor changes in the models, a reproduction of this table may not result in exactly the same numbers.

Table 66: Location of boundaries within the scenarios in ESP/2004

Area bounds	Boundary 1 (Area 1-2)	Boundary 2 (Area 2-3)	Boundary 3 (Area 3-4)	Boundary 4 (Area 4-5)
HP/M (distributed)	1 500 m	2 440 m	2 880 m	3 520 m
HP/R (co-located)	1 500 m	2 140 m	2 960 m	3 210 m
MP/P (co-located)	1 500 m	2 820 m	3 260m	4 050 m
MP/P (distributed)	1 500 m	2 820 m	3 270 m	4 200 m
MP/I (distributed)	1 500 m	2 890 m	3 380 m	4 300 m
MP/M (distributed)	1 500 m	2 840 m	3 280 m	4 020 m

NOTE: The estimations in table 66 have been carried out in a certain order, and all these systems operated with at least 6 dB of noise margin. First a system was considered that has the shortest reach in the given scenario. Next the system was considered that has the second shortest range in the same scenario, and so on. In addition, the following simplifications have been applied:

- Boundary 1 is fixed to 1 500 m. (*This is the right-hand boundary of area 1, representing the maximum deployment distance of VDSL.*)
- In scenarios where both HDSL.2B1Q/2 and HDSL.CAP/2 systems are present, boundary 3 represents the shortest reach of the two.

Handling disturbers in "distributed" topologies

Table 67 summarizes how to deal with the various disturbers in distributed topologies.

- Crosstalk from area 1 systems:** If a victim system is deployed beyond area 1, assume that VDSL is terminated at boundary 1 and disturbs the victim system by attenuated crosstalk.
- Crosstalk from area 2 systems:** If a victim system is deployed beyond area 2, assume that SDSL 2 048 kb/s is terminated at boundary 2 and disturbs the victim system by attenuated crosstalk.
- Crosstalk from area 3 systems:** If a victim system is deployed beyond area 3, assume that HDSL is terminated at boundary 3 and disturbs the victim system by attenuated crosstalk.
- Crosstalk from area 4 systems:** If a victim system is deployed beyond area 4, assume that SDSL 1 024 kb/s is regenerated and neglect the effect of the additional crosstalk by the repeaters somewhere between the LT and NT. However, the crosstalk that is generated by the SDSL 1 024 kb/s system at the end of the line should be taken into account.

Table 67: Summary of the disturbers to be considered in a distributed topology

Disturbers when victim NT is in				
Area 1	Area 2	Area 3	Area 4	Area 5
VDSL	X-1	X-1	X-1	X-1
SDSL-2048	SDSL-2048	X-2	X-2	X-2
HDSL	HDSL	HDSL	X-3	X-3
SDSL-1024	SDSL-1024	SDSL-1024	SDSL-1024	Reg. SDSL-1024
ADSL	ADSL	ADSL	ADSL	ADSL
ISDN	ISDN	ISDN	ISDN	ISDN

Reg-SDSL-1024 means regenerated SDSL 1 024 kb/2 systems
X-n means attenuated crosstalk from area-"n"

Handling disturbers in "virtually co-located" topologies

Table 68 summarizes how to deal with the various disturbers in virtually co-located topologies.

- Crosstalk from area 1 systems:** If a victim system is deployed beyond area 1, assume that a disturbing VDSL is terminated at boundary 1 and disturbs the victim system by attenuated crosstalk.

NOTE: The concept of "virtual co-location" conflicts with the concept of attenuated VDSL crosstalk up to area 5, but the impact of such crosstalk becomes ignorable beyond some distance.

- **Crosstalk from area 2 systems:** If a victim system is deployed beyond area 2, convert the disturbing SDSL 2 048 kb/s into an SDSL system with lower bitrate. For victims deployed in area 3 or 4, this bitrate equals 1 024 kb/s. For victims deployed in area 5, this bitrate equals 512 kb/s.
- **Crosstalk from area 3 systems:** If a victim system is deployed beyond area 3, assume that HDSL is regenerated and neglect the effect of the additional crosstalk by the repeaters in the middle of the line. However, the crosstalk that is generated by the HDSL system at the end of the line should be taken into account.
- **Crosstalk from area 4 systems:** If a victim system is deployed beyond area 4, assume that a disturbing SDSL 1 024 kb/s is regenerated and neglect the effect of the additional crosstalk by the repeaters in the middle of the line. However, the crosstalk that is generated by the SDSL 1 024 kb/s systems at the end of the line should be taken into account.

Table 68: Summary of the disturbers to be considered in a virtually co-located topology

Disturbers when victim NT is in				
Area 1	Area 2	Area 3	Area 4	Area 5
VDSL	X-1	X-1	X-1	X-1
SDSL-2048	SDSL-2048	SDSL-1024	SDSL-1024	SDSL-512
HDSL	HDSL	HDSL	Reg-HDSL	Reg-HDSL
SDSL-1024	SDSL-1024	SDSL-1024	SDSL-1024	SDSL-512
ADSL	ADSL	ADSL	ADSL	ADSL
ISDN	ISDN	ISDN	ISDN	ISDN

Reg-HDSL means regenerated-HDSL 2 pairs systems
SDSL-512 means a 512 kb/s SDSL system (or lower if that rate will not work either)
X-n means attenuated crosstalk from area-"n"

9.1.4 Loop models within ESP/2004

The models for transmission and crosstalk are specified in table 69. For the sake of simplicity, all effects related to the impedance for both the insertion loss and the crosstalk calculations are ignored. The impedance of 135 Ω is selected for all the systems, even if this is not correct for such systems like e.g. those belonging to the ADSL family.

Table 69: The involved models and associated parameters to account for various cable characteristics

Transmission	Two-port model	TP100	The TP100 cable model is described in annex A of the VDSL specification (TS 101 270-1 [11]). Bridge taps are assumed to be absent, and the characteristics of all cable sections in a cascade are assumed to be equal per unit length.
	Reference Impedance	$R_N = 135 \Omega$	The impact of the levels of signals, as a function of the termination impedance, is ignored for computational convenience. For calculating signal loss, assume that source and load impedance are $R_N = 135 \Omega$, for each xDSL system under study.
Crosstalk	Cumulation See clause 8.3.2		The FSAN sum for crosstalk cumulation, as specified in clause 8.3.2.1, applies for cumulating the power levels of M individual disturbers into the power level of an equivalent disturber.
	Coupling See clause 8.3.3	$K_{xn_dB} = -50 \text{ dB}$ $K_{xf_dB} = -45 \text{ dB}$ $f_0 = 1 \text{ MHz}$ $L_0 = 1 \text{ km}$	The basic models for equivalent NEXT and FEXT diagram for two-node topologies, as specified in clause 8.3.3.1, applies for modelling the equivalent crosstalk coupling.
	Injection See clause 8.3.4	$H_{xi} \equiv 1$	The impact on the levels of crosstalk noise, as a function of the termination impedance, is ignored for computational convenience (equivalent to $H_{xi} \equiv 1$).

9.1.5 Scenarios within ESP/2004

To carry out a spectral management study for a "new system" under ESP/2004, the six scenarios in table 70 are to be evaluated according to the reference method. This means that the change in performance is to be evaluated for each broadband system in the mix of each scenario, when the mix changes from the "reference mix" to the "modified mix" (as specified before in table 62).

Table 70: The combination of mixtures and topologies that form the scenarios of ESP/2004

Scenario	Mix	Topology
1	HP/M	distributed
2	HP/R	co-located
3	MP/P	co-located
4	MP/P	distributed
5	MP/I	distributed
6	MP/M	distributed

In addition, the following applies:

- All the systems shall have at least 6 dB of noise margin.
- The frequency resolution to be used in the simulations shall be 4,3125 kHz or smaller.
- A flat level of -140 dBm/Hz representative of background noise shall be added to the overall crosstalk noise.
